We have thus, so far as the Allies are concerned, four marginal resources, namely, our small normal surplus, the embargo, an abnormal surplus to be created by stimulated production, and a further surplus to be created by a reduction in our consumption. Our resiliency of resources in these four directions, principally the latter, is such that we can, if we have the will to do so, maintain the strength of the Allies and of our own people. All talk of famine is mere hysteria. Our world-food situation is not to be interpreted as famine; at worst, it is to be interpreted in terms of soldiers for France, or, alternatively, it can be interpreted in terms of larger ship-building programs.

As to what our marginal possibilities of exports to the Allies may amount to, we can gain some idea if we review the situation since our last harvest—a period coincident with the period of the Food Administration. Because of the enormous demand upon us during the previous year, we entered the last harvest with our national stocks of cereals practically exhausted. We carried over less foodstuffs to the new harvest than at any time during many years. Our herd of hogs, which is our most ready and prolific source of fat, was apparently below normal as the result of previous years' heavy exports to the Allies—and we were faced with increased demands.

Owing to the fine activities of our Department of Agriculture and to the patriotic action of our farmers, a largely increased area in foodstuffs was planted for the 1917 crop, but because of weather conditions, the harvest was greatly damaged. Our wheat yield in proportion to the area planted was the lowest in many years, and in actual quantity we had no practical export-surplus over our normal consumption of this grain. A large portion of our enormous acreage of corn failed to reach maturity, and thus its food-value fell far below normal.

If we reduce our annual production to its actual nutritive value we find that our production of 1917 is about 7% below the average of the three previous years, and in the same terms we exported an average of about 10% of our production. Yet we expect that our exports to the Allies, measured in nutritive values, will this year again reach approximately the average of the three previous years. In other words, we have had to reduce our consumption by about 7% this year in order to do our duty by the Allies.

With the increased prosperity in wide sections of the community engaged in agricultural and industrial pursuits the standards of living in these regions have been raised and the food consumption of the American people materially increased. How acute this is may be indicated to you by the fact that our consumption of beef products apparently increased by 10% during 1917. We therefore had to stem the tide of increasing consumption.

The necessity of this reduction in consumption falls unequally on various commodities, depending upon their durability, their convenience in shipping, the food habits of the people we feed, etc. Nor are we able to anticipate in advance exactly what may be required from us in these disturbed times. As illustrating both points—we originally calculated that we must ship 100,000,000 bushels of wheat this year. Owing to the deficiencies in the importation to the Allies from more remote markets, we have had to raise this total to 160,000,000 bushels and to do this out of a home surplus of only 20,000,000 bushels over our normal consumption. Therefore, to feed the Allies we must take from our normal consumption of wheat, not 16% as we originally estimated, but 30%. Thus we have been compelled to increase the intensity of our conservation during the last half of the year. Wheat products are vital as a basis of war-bread to Europe because of their durability in transport and on account of the milling and baking equipment of the European peoples.

Another instance of the disturbances in original plans arose from the two and one-half months of storm weather which paralyzed our railways. Our hogs were blockaded on our farms, and the situation not only rendered difficult the supply of meats in this period, but the flood of animals released with improved transport overcharged our storage and shipping capacity. We therefore were compelled to relax our conservation efforts for a short period until the flood passed. You can thus readily see that there can be little fixity of policy in an administration that is dependent on the exigencies of war and shipping. We must alter our tactics from day to day to meet the changing world situation.

The reduction of consumption during this year has been vital. To secure it we had three alternatives of action:

First, rationing.

Second, by bidding up prices in the purchase of Allied supplies until the consumption falls.

Third, by obtaining a voluntary reduction of the individual consumption, simpler living, economy in waste, substitution of commodities that we have in greater abundance for those that we have to export.

Any system of positive rationing of the United States bristles with difficulties. Half the population are either producers or live in intimate contact with the producer and therefore cannot be restrained in their consumption by any rationing. The consumption of the very poor is not beyond the necessities of their health and strength. Our industrial population varies greatly in its habit of consumption of any given commodity in different parts of the country. Furthermore, this class of the com-

munity varies greatly in its habit in different sections of the United States as to the commodities it consumes. For instance, the worker in the South consumes perhaps not more than two pounds of wheat products per week per capita, whereas in some parts of the North he consumes eight pounds. Rationing of wheat on any broad national line would increase the consumption beyond necessity in the South and decrease it in the North below necessity. Furthermore, to adopt rationing as a positive system would cost the Government \$10,000,000 or \$15,000,000 annually in bureaucratic expense, as we should have to place tickets and coupons with every householder, and behind these tickets would have to be erected a vast administrative organization.

It has been believed by many that the best adjustment in consumption would be obtained by increasing price-levels in that commodity in which it is desired to reduce consumption by simply bidding up the price for Allied supplies. I feel strongly, however, that reduction of consumption to the extent that we require by an increasing price is simply and purely to place certain commodities out of the reach of those classes of the community who have not the purchasing power, and that this whole conception is simply conservation for the rich and against the poor. The adoption of this principle of rising prices would mean that the poorer sections of our community would have paid in suffering and the richer classes would have paid in price many score times the cost of any other system of reduction.

Furthermore, if we are to increase the price of our foodstuffs merely to decrease their consumption, we must enter a vicious circle of constant re-adjustment of wages, for our working people must live. Beyond this, again, we could no doubt reduce the consumption, for instance, of sugar by 20%, if we doubled the price, but to double the price of sugar alone means an annual drain on our population of \$600,000,000, and this \$600,000,000 would go into the hands of a vast number of middle-men and would give rise at once to profiteering, discontent, and would lay the foundations for social revolution.

In considering the whole problem, we determined upon a line not hitherto applied and the success of which we believe will be one of the remembered glories of the American people in this titanic struggle, that is, that we should place the reduction of consumption on a voluntary basis. We felt that we could secure voluntary reduction by savings which would be made not from the necessities of the poorer classes of the community, but in the saving out of plenty by the more fortunate classes.

Voluntary conservation has also a moral side, to my mind, of some importance. By it we are appealing directly to the self-sacrifice of the people of the United States in the carrying on of the War. I do not believe that there is another nation in the world in which the proportion of individuals of a willing sense of self-sacrifice is so high as in this people of ours, and in which a sufficient voluntary reduction could be obtained. Our program therefore has been a hazard upon the number of people of this kind in the United States. This basis of reduction gave some trepidation to the Allies, for fear of

its failure, but I am happy to say that we shall have performed our national duty, the Allies will have been fed during this harvest-year, so far as the obligation falls upon us, almost wholly upon a voluntary footing. Far beyond this, it is justifying us in our belief in the high idealism of the American people.

We have had some criticism from individuals who believe that they should not be called upon to do more than their neighbors willingly do. In response to this, my feeling is that our Army does not fail to go over the top because there may be two or three slackers hiding in the trenches.

Aside from the prime necessity of protecting our independence and our institutions, there is but one possible benefit from the War, and that is the stimulation of self-sacrifice in the people, the lifting of its ideals and the diversion of its peace tendencies to the purely material things of life, to a strengthening of its higher purposes. I do not say that such compensations are full compensation for war, but they are at least an amelioration of the terrible currents that are threatening our existence. Therefore we felt that if there could be brought home to the sense of every American household the necessity of this personal and individual sacrifice, we would have spread the opportunity for service beyond those who sacrifice in giving their sons to immolation on the national altar.

To accomplish this requires education; it requires an intimate understanding for each man, woman, and child in the United States of the objectives of the Government and the duty that falls upon them. We have called upon the millions of women and men in the United States with an unfailing reply. We have created great numbers of committees who have worked with the utmost devotion. We have penetrated each of our 20,000,000 households periodically with literature and we have plastered the hoardings of the country with posters. We have secured the co-operation of the manufacturers and distributors of food. We could not have attained this had we not had the absolute devotion and team-work of every newspaper in the United States. Our every appeal has, through this gigantic influence, received an immediate and prompt distribution. Without this incessant, voluntary, liberal support, our plan would have been impossible.

There is another side of all this to those of us who have lived behind the German lines. No hour goes by but our hearts are haunted by the scenes of long lines of emaciated women and children who today and for three years have gathered in Belgium for their daily bread from America. That pittance—their all—represents scarcely the waste from American tables. This winter these lines have, for the first time during the War, gathered in the poorer sections of England, France, and Italy. Not only should this pull at our hearts; it is a menace to our very safety. In the presence of a common enemy we sit at a common table with all the defenders. Is the daily call of the Food Administration for less waste, for simpler living, to eat only for strength, not a call to conscience? Is it not a vital call of defence?

As to next year, we can formulate no plans until we know the harvest. Our farmers this year, despite great handicaps, are making the greatest of efforts. The weather is our real and final food-controller. If we have a bumper crop we can save many ships from long voyages. Even without a bumper crop, we could save more food next year. A crop failure, so far as to cause famine, is humanly impossible; the worst might compel more conservation.

The reduction of food-supplies below normal and all of the commercial difficulties connected with the aggregation of these reductions in disturbance to inland and overseas transportation have caused new currents in our economic life, and the Food Administration has, by force of necessity, had to pioneer untraveled paths in the economic jungle of war as an incident to its main purpose. For instance, there is a great deal of discussion throughout the country over price stabilization by the Government. That discussion is partly academic, partly misinformed, and most of it without any knowledge or admission of the total economic dislocations imposed by the War. So far the Government has developed no principle of price-fixing as a broad economic policy. Dislocations apply first to one great commodity and then to another, and therefore our aspect of the problem is to deal with them as they arise, commodity by commodity. We are dealing with conditions and not with theories.

Disturbance through shortage in supply, failure of inland or overseas transport, or because of the other matters with which we must contend, all lead to hardship on either producer or consumer. Our view is to review the alternative courses of action and to choose that course which leads to the lesser hardship. We are not exploiting economic reform or economic revolution. Up to the present time, and as far as I can see at the moment, what may be called the incidental policy of the Government is the only one that it will be necessary to apply, and it may be summarized in the following statement:

Every export from the United States today is under control. It is controlled that it may serve the positive military ends of the Government. All of our exports are directed to supporting the Allies, or, alternatively, where we deal with neutrals, to get the *quid pro quo* for the sacrifice of our commodities. Thus our food exports are directed toward but a few hands on the other side of the water.

With the shortage in shipping, it has been necessary for these governments to put available shipping into use for the common purpose, in order to secure the utmost expedition in loading and discharging at ports of call, and to arrange that it be loaded with the most advantageous commodities from a national point of view.

It was found by experience to be absolutely impossible to trust to the normal commercial agencies to select the prime commodities necessary for national existence among the Allies and to trust to the incidental operation of trade to maintain the maximum handling of shipping. Furthermore, these commodities are distributed by their governments under rationing systems, and thus must, in

any event, come into government hands. Therefore the European governments have been compelled to undertake, as the consequence of shortage on supplies, the single-handed purchase of their supplies both for civil and military purposes. There has thus grown up an enormous consolidation of buying of 120,000,000 European people, a phenomenon never before witnessed in the economic history of the world.

Furthermore, we have aggregated in this country something like 2,000,000 men under arms, and we shall probably expand our forces to three or five million before we are finished. The buying for these men is necessarily concentrated in one agency, instead of 5,000,000 separate agencies as before, and we have thus a second great engine growing up in our midst as a necessity of war conditions. In order that these two buying agencies should not get in each other's way, it has been necessary to place them under joint direction. In the final outcome, therefore, we find ourselves in the presence of a gigantic monopoly of buying just as potent for good or evil as any monopoly in selling, and in many instances either making or influencing prices. Therefore, not through any theory, but through an actual physical fact, the price made by this gigantic buyer dominates the market.

This is price-fixing in a light never contemplated in economic history or theory, and it is time that economic thinkers denude themselves of their procrustean formulas of supply and demand and took cognizance of it. In commodities where this situation arises, the Government must necessarily regulate the price, and all theories to the contrary go by the board. So far among food commodities only wheat is positively involved, and pork prices are influenced by the volume of buying.

It is entirely possible for the Government to make these purchases to the best advantage of the Allies and of the Army and Navy and to disregard totally the civilian population, either the consumer or the producer. Where these purchases aggregate such a volume as to make inroads on the normal consumption of the civilian, it would mean that the residue would go to the highest bidder. This would be conservation again for the rich and not for the poor, with a vengeance. Had we allowed this to go on in wheat, flour would today be \$40 per barrel, instead of at a universal price of practically \$12.

The producer is also subject to damage by these great buying agencies. Production of food does not take place evenly over the year; it is seasonal. It is entirely possible for such a monopoly to manipulate prices in the season of surplus marketing to figures below the producer's cost. Again, transportation both inland and overseas is subject to every vicissitude of war. Temporary stoppages in transport can produce speculative disaster unless some stability is given to markets. Therefore both sides, consumer and producer, must be safeguarded by wise direction of this buying power, and this is bound to result in price regulation in certain commodities in just protection to both.

But right at this point arises to me a fundamental principle in national war economics. I do not believe

that any person in these United States has a right to make one cent more profit out of any employment than he would have made under pre-war conditions. I do not care whether this refers to the farmer, to the laborer, to the manufacturer, to the middle-men, or to the retailer; to me, every cent taken beyond this standard is money abstracted from the blood and sacrifice of the American people.

I do not believe that extortionate profits are necessary to secure the maximum effort on the part of the American people in this War. If we are going to adopt that theory, we have admitted everything that has been charged against us of being the most materialistic, the most avaricious, and the most venal of people in this world. If we are going to admit that the Government, in order to secure the supreme efforts of its citizens in production must bribe them with money for this extra exertion, we have admitted a weakness of American character, of American civilization, and of American ideals that puts us on a plane below German kultur.

Do not mistake, I am not saying that prices and wages should return to the pre-war normal, because the incidence of war before we joined in it had lifted our costs of operation, and there must be compensation in every direction. Nevertheless, I hold that any man who has made more than his necessary living out of the cost this nation is giving in blood of the boys we are sending to France should not stand out as a benefactor to his community.

I have had this statement met before now with the expression that it is dreamy idealism, but I have found no individual who was prepared in his own instance to defend any such line of action. It is true that this doctrine has been made law only to the larger food trades. I am confident that profiteering has from a national point of view disappeared in the regulated food trades, and in consequence my belief is that it should be applied generally to all business in this community, and it is also my belief that before we are finished with this War, that will have been done.

To me, this goes much further than the mere ease of the individual and the blame that may be attached to him. As I have seen this War develop from an active participation in its backwash and misery since its first day, I have seen growing out of the masses of people in every country aspirations for a great economic change. That change, broadly, will be, in the view of extremists, that those who work with their hands will obtain a larger portion of this world's goods and those who work with their brains will obtain less, while those who do not work will probably obtain nothing.

If we are to bring about this economic change in an orderly and American way, and not by convulsions during the period of recuperation from the War, we must lay the foundations for it now. None of us wants a repetition in the United States of the history of the last twelve months of Russia. The proper social development of this country along these lines fills the background of all men's minds and its proper guidance rests upon the liberal and thinking men of the country.

The enforcement of this law against profiteering in the food trades is a considerable part of our anxieties. In order to determine how far we have succeeded, that is, how far the margin between the producer and consumer has been diminished, we maintain positive data in our organization. To illustrate this, we have calculated a price-index based upon the food-values of the principal commodities. For instance, a rise of a half-dollar per dozen in eggs would be a good headline, but it is not as important to the country as a rise of a cent per loaf in bread. Upon this basis we find that since the Food Administration was founded the price of food commodities has increased 18% to the producer and at the same time it has decreased 12% to the consumer. The margin is thus smaller by 30%, in fact, it is now so narrow that price-charges to the producer directly reflect to the consumer, and the Food Administration has to take all of the curses of both sides.

This has been accomplished largely by voluntary co-operation of the food trades. Ninety-five per cent of our traders desire to serve the common interest and the measure of their co-operation is one of the most illuminating proof of the high sense of service in our people. While isolated instances will occur, I am convinced that at no time in the last three years has there been as little speculation and extortion in the nation's food as there is today.

Another economic theme which the Food Administration has had to pioneer is that of saving. Speaking broadly, we have some thirty-six millions of able-bodied manhood. We have already had to divert two millions of these men to actual arms. Beyond this we have had to divert a vast number of men to provide munitions not only for ourselves but for the Allies. We have had to divert vast numbers of men to the provision of the raw materials for these shops. We have had to set aside larger amounts of our foodstuffs for the Allies, and consequently there was a diversion of farm production to this purpose. Altogether, a rough calculation indicates that already we have diverted from eight to ten million men from their normal occupations toward war and the products it requires. That is from one-quarter to one-third of our normal productive units. It is possible that we can increase the exertion of the remainder of our productive population by eliminating non-essential labor, by more intensive labor and longer hours, by the application of woman's labor, by putting the boys into labor earlier than otherwise, and can make up some of the gap in our productive units. We cannot, however, compass the whole, and the deficiency can only be overcome by the reduction in the consumption in commodities.

This does not apply to food alone, it applies to every commodity of which we consume more than is necessary for our health and comfort. We must strip to the bone in order that we may afford the economic luxury of the diversion of this portion of our productive power to the destruction of war. If we do not, our exertion in this War will stop short of the task imposed upon us, and we cannot look to victory with any assurance.

When we survey the economic field in detail, we neces-

sarily find difference in the degree of the essential character of commodities and labor. There are some commodities and some labor that we do not require at all, and all that we can turn to our shipyards, our munition works, and the Allied food supply is a contribution to war.

Too much economic thinking is done in terms of money. If we could, like Germany, reach that point of economic balance where the increased productivity of our home population and the decreased consumption of our home population affords the complete supply of men and commodities needed in war, we could fight for the next fifty years without economic loss. Money becomes purely the counters through which distribution of those commodities and labor is obtained.

If we subscribe for one Liberty bond from our normal surplus income, we will have furnished the Treasury with some of its necessary counters, but if we subscribe for another Liberty bond from the savings that we make on the consumption of commodities and labor we will have contributed these commodities or this labor to the War, and our second bond will have done two duties. Without it, neither the Treasury will have enough counters, nor our fighting men enough supplies. The subscription of Liberty bonds is no sacrifice for the American people. The Government is agreeing to re-pay you. It is the saving that we make in the consumption of commodities and in the employment of labor that is the sacrifice for the winning of this War.

Another prime economic theme by which I am impressed in this War is this: The American ideal in executive work is efficiency, but efficiency does not alone mean the best appliances and the greatest number made for the least cost. In war it involves a new factor that transcends all others—speed. Many of our present difficulties arise from our inability to get away from our trodden interpretation of the word "efficiency," and many of them from the fear of our executive officers of criticism if they fail in popular interpretation of this term.

In this light the measures taken, the results attained, cannot be judged by the microscopic inspection of the threads in the tapestry—its broad lines, its inspiration, must be attained quickly, not by years of careful development. It will be of no avail to us if we lose a war, though it cost less per unit than any war in history.

We are a discouragingly critical people. Those of us in Washington are damned if we do, and damned if we don't.

There is but one real test for Washington. Our game is to win the War, and the test is, do we keep our eyes on the ball? For, friends, this people will be cursed for the next ten generations if we don't. Nor does this test apply to Washington alone. We in the Government can often criticize also, and our right of criticism lies against that minority of people who hope for self-interest out of winning the War. This Government is nothing more than the expression of the people, and if we are to win the War, it will be only because every man, woman, and child charges himself daily and hourly with the test, does this or that contribute to win the War?

Galena in Wireless Apparatus

Some months ago the superintendent of the Scranton mine in Tootoe county, Utah, received a communication from the Bureau of Standards, at Washington, asking him to forward several hundred pounds of galena. Accompanying this request was a statement that the galena from the Scranton mine was particularly valuable as forming a part of wireless apparatus. It developed later that the Bureau of Standards had secured, from some of the technical men at Washington, a series of samples of galena ore from various mines in the United States. Small fragments or crystals of galena are used as contact-points on portable wireless-telegraph outfits. These crystals are set in a cadmium alloy known as Wood's metal, which has a melting-point below the boiling-point of water. The Bureau of Standards, in testing the various samples of galena for the purpose mentioned above, discovered that the galena from the Scranton mine possessed some properties that made it desirable above that of any other mineral tested. It had earlier been discovered that in a large piece of galena there were certain small particles that would effectively serve the purpose, but the mass of mineral was either worthless or so weak in its properties that it was not desirable for the use intended; also that out of several thousand fragments perhaps one or two from the same mass could be utilized. The galena from the Scranton mine was uniformly good. In order to discover what peculiar property the galena from this mine possessed, very careful chemical analyses were made in an effort to determine the presence of some element not contained in other ores. Tests were also made on the radio-active properties of the mineral; the galena was studied under reflected light, and its crystallographic, physical, and electrical characteristics were carefully investigated. The most refined examination by the best talent in the Government service has been unable to discover the reason for the galena from the Scranton mine possessing the especially desirable characteristic not shown in other ores. A member of the Bureau of Standards was recently sent from Washington to Salt Lake City for the purpose of getting a supply of suitable galena. The mine from which the mineral was taken has orebodies of combined zinc and lead, with a little silver. The ore occurs in limestone and is thoroughly oxidized, so that the occurrence of galena is rather uncommon. It took two weeks of careful search and considerable work to collect 300 lb. of galena. It might be noted that in a mine whose ore appeared to be identical in every respect, situated some distance to the west, the galena proved valueless for the wireless telegraph. The whole problem of securing suitable contact-points seems to be one of trial in actual operation rather than by determination through any known analysis.

SODIUM CHLORATE is in active demand at 18c. per pound, with sales reported for prompt delivery at 25 to 26 cents.

Formulas for Mine-Valuation

By W. W. WHITTON

The tables in common use for the valuation of mines are based on what is commonly known as the Hoskold formula. In 1877 was published the first edition of the 'Engineer's Valuing Assistant' by H. D. Hoskold; a second edition appeared in 1905. In this book is to be found an algebraic deduction of the formula, together with extensive tables of mathematical equivalents. Smaller tables are to be found in Hoover's 'Principles of Mining' and in Finlay's 'Cost of Mining.'

In this paper I have undertaken to give a deduction of the Hoskold formula, and to show that this formula does not correctly represent the algebraic relationship between the several quantities recognized as entering into the valuation of a mining investment, and that, at ordinary rates of interest and usual years of life, the factors based on the Hoskold formula are in error by as much as 20%. It is probable that this error has passed unnoticed because of the algebraic method commonly used for its deduction. In this it is assumed that the annual dividends of a mining investment constitute an annuity, and the algebraic notation of actuaries is employed. This notation is confusing to those not familiar with actuarial calculations, and I shall therefore develop the formulas by simple algebra. The deduction so performed is longer, but it will be more easily grasped by the engineer.

The Hoskold formula attempts to express the algebraic relationship between present value or capital, rate of interest, and the term or years of life of a mining investment. By so doing the attempt is made to place mine-valuation upon the same basis as the ordinary investment of capital, as for instance the purchase of a mortgage or a bond. On investing capital in a bond the years it has to run is not a matter of great importance, because the investor understands that a sinking-fund is being created, which, at the expiration of the term, will restore the capital. A mining investment, however, is of the class known as a wasting asset, or of that class in which the payment of returns on the investment necessarily results in the destruction of the property in which the capital is invested. Hence the term or years of life of the mine is a matter of vital importance. Other classes of investments give at least some guarantee of the return of capital, and it would be desirable that mining as far as possible should be placed upon the same basis: we should, therefore, in theory at any rate, provide for the return of the capital to an investor, as well as allow for the payment of interest according to the risk assumed.

Mining companies do not generally establish a sinking fund that will return the capital to an investor. Possibly they should do so, as has often been claimed; but it ap-

pears that this should be left to the investor, except in special cases. During the early stages of the development of a mine the stock may be worth intrinsically but a small fraction of its par value; likewise, when the payments of large dividends are assured, the same stock may be worth many times the par value. Investors may have purchased stock throughout the entire range of prices, and the mine officials have no way of determining the price at which stock was acquired. Therefore the attempt to provide for the return of capital by mining companies seems to be improper, but it is none the less a matter of importance to the individual investor. Hoskold appears to have been one of the first engineers to recognize this principle in mine-valuation, and he has shown that each dividend received by the investor is to be regarded as composed only in part of interest on the investment, and that the remainder in theory must be set aside to provide a sinking-fund that will return the capital at the exhaustion of the mine. In other words, this balance is to be regarded as an installment to be paid annually into the sinking-fund, and this portion must be of such amount that, when re-invested in a safe security, as, for example, when deposited in a bank at 4% compound interest, it will amount to the sum originally invested at the time of exhaustion of the mine.

This theory of the formation of the sinking-fund may be made clearer if the investor, in the case given by Hoskold, will regard the capital he has put in the mine as a 'loan' to the mine. The mine as the 'borrower' is to pay a proper rate of interest on the loan, and, of course, must return the amount borrowed to the lender. In view of the fact that, on the exhaustion of the mine the 'borrower' will be powerless to return the capital to the lender, each dividend must consist of interest and an additional amount sufficient, if reinvested at compound interest at 4%, to equal the amount borrowed when the mine is exhausted and dividends cease.

Upon this Hoskold has based his formula; it is sound in theory, but as an hypothesis it is incomplete. There are several ways in which the amounts paid as interest and those paid into the sinking-fund may be apportioned, and also in which the sinking-fund may be accumulated. Hoskold's hypothesis is that interest is to be paid at the stipulated rate on the entire sum originally invested during the total life of the mine; this requires a constant amount of interest each year to be taken out of the dividend, hence there is a constant installment paid annually into the sinking-fund. I regard this division of the dividend between interest and sinking fund as incorrect, and shall attempt to so demonstrate, after giving a deduction of the Hoskold formula.

The algebraic quantities entering into the deduction of the Hoskold formula are as follows:

j = the rate at which the sinking-fund installments are to be placed at interest. This is taken at both $3\frac{1}{2}$ and 4% in the United States; in England, rates of 3 and $3\frac{1}{2}$ % are used. For 4% $j = 0.04$.

i = the rate to be realized on the investment. This may vary in practice from 4 to 30, or even 40%. It is itself composed of several factors. It must be greater than j , the rate that can be realized safely on an investment with practically no risk of losing the capital. Other elements entering into this factor are that it must be great enough to compensate the investor for the risk assumed and for the labor of supervision of the investment, and probably a desirability factor, an insurance factor, and others. This matter has been discussed at some length in Burnham's 'Modern Mine Valuation.'

d = the amount of annual dividend (in dollars).

n = the term of the investment or years of life of the mine.

V = the present value of the investment.

According to Hoskold's hypothesis, each annual dividend d is the sum of two quantities, namely, interest and a payment into the sinking-fund. The amount of the annual interest on the capital V is Vi ; hence the amount of the sinking-fund installment is $d - Vi$. Both V and d being constants, the annual payments of interest and into the sinking-fund are constants throughout the interval of n years.

The first installment paid into the sinking-fund will remain at compound interest at rate j for $n-1$ years; hence, at the end of the term of n years, it will amount, according to the well-known formula for the amount of a sum at compound interest, at the exhaustion of the mine, to $(d - Vi) (1 + j)^{n-1}$.

Similarly the second installment paid into the sinking-fund will remain at interest at rate j for $n-2$ years, and at the exhaustion of the mine will amount to $(d - Vi) (1 + j)^{n-2}$. The third installment similarly will amount to $(d - Vi) (1 + j)^{n-3}$. The hypothesis is that, when the mine is exhausted in n years, the sinking-fund will amount to V , that is, the amount of the original investment. Hence

$$V = (d - Vi) (1 + j)^{n-1} + (d - Vi) (1 + j)^{n-2} + (d - Vi) (1 + j)^{n-3} + \dots + (d - Vi) (1 + j)^2 + (d - Vi) (1 + j) + (d - Vi).$$

As $(d - Vi)$ is a common factor, this equals the expression

$$V = (d - Vi) [(1 + j)^{n-1} + (1 + j)^{n-2} + (1 + j)^{n-3} + \dots + (1 + j)^2 + (1 + j) + 1].$$

The expression within the brackets is a geometric series with a ratio $(1 + j)$, and the sum of this series is $\frac{(1 + j)^n - 1}{(1 + j) - 1}$; substituting this value for the sum of the brackets we have

$$V = (d - Vi) \frac{(1 + j)^n - 1}{(1 + j) - 1} = (d - Vi) \frac{(1 + j)^n - 1}{j}$$

The above equation contains all of the factors entering into the deduction of the formula; therefore, without further substitution, it may be employed for the computation of the Hoskold factors, but for this purpose it should be simplified by grouping the terms of like order. The equation thus becomes

$$V = d \frac{(1 + j)^n - 1}{(1 + j)^n - i - j}$$

Assuming an annual dividend of one dollar, or unity, Hoskold's factors are obtained by substituting the required values for i and j . As a typical case, and as an aid to the discussion of the formula, take a mine with an expected life of 10 years, paying an annual dividend of \$1000, the rate to be allowed on the investment to be 10%, with the sinking-fund placed at interest at 4%. From Hoskold's tables the value of this investment is \$5455.80691. The following redemption table will illustrate the application of the Hoskold formula:

Year	V	Dividend	d	Vi	$(d - Vi)$	Amount of sinking-fund
1	\$5455.81	\$1000	\$545.58	\$454.42	\$646.78
2	5455.81	1000	545.58	454.42	621.91
3	5455.81	1000	545.58	454.42	597.98
4	5455.81	1000	545.58	454.42	574.98
5	5455.81	1000	545.58	454.42	552.87
6	5455.81	1000	545.58	454.42	531.61
7	5455.81	1000	545.58	454.42	511.16
8	5455.81	1000	545.58	454.42	491.50
9	5455.81	1000	545.58	454.42	472.60
10	5455.81	1000	545.58	454.42	454.42
						\$5455.81

The foregoing table, constructed on the hypothesis upon which the Hoskold formula is based, shows that the annual dividend of \$1000 is divided, throughout the 10-year life of the mine, into two constant parts. The dividend of 10% on the capital of \$5455.81 requires \$545.58; and the balance, which is \$1000 less \$545.58, or \$454.42, is paid into the sinking-fund, where it accumulates at 4% compound interest. The sixth column gives the amount of each installment, accumulated at 4% interest, compounded annually, at the end of the tenth year. The sum of this column is the amount of the original investment. The last column gives the total amount in the sinking-fund at the end of each year, and the error in the Hoskold formula is plainly exhibited by this column. Consider, for example, the amount in the sinking-fund at the close of the ninth year, which the table gives as \$4809.03. Of the original capital put into the mine there remains in fact only the difference between the total in the sinking-fund and the amount originally put in, or \$5455.81 less \$4809.03, which is \$646.78; and this amount only is exposed to the risk that calls for the payment of 10% interest on the investment. The remainder of the original capital has passed through the hands of the investor and has been placed in some safe security bearing 4% interest. It is, therefore, unquestionably a fallacy to require a mine to pay a high rate of interest on the entire amount originally invested during its entire life; and more especially is

this true when, as in this example, the value of the remaining one year's dividends is but \$909.09. Imagine a borrower that has paid back all of a loan of \$5455.81 except \$646.78, which he had borrowed at 10% interest, and that he still is required to pay interest at 10% on the amount originally borrowed.

This error in the Hoskold formula and the factors based thereon seems to have passed unnoticed. The only direct reference to it that I have seen is that Inwood makes the comment, regarding the factors to be used in valuing loans, that the terms of such loans are onerous to the borrower. It even appears to be commonly assumed in mining literature that Hoskold's formula is based on the assumption that the mine does pay interest only on that portion of the capital unreturned to the investor, whereas the direct opposite is the case. Nor is this error small in amount. As I shall later show, the true value of the investment given in the above table is \$6591.37, which is practically 20% greater than the Hoskold factor.

I shall now give the deduction of a formula that rectifies this error in the Hoskold formula, and which I believe to be the correct formula to be used for mine valuation. This is based upon the same assumptions as the Hoskold formula, with the added provision that interest shall be paid at the risk-rate i only upon the unreturned capital, and that the unreturned capital shall be the amount of the original investment less the amount in the sinking-fund. The amount in the sinking-fund at any time is the amount paid into this fund out of dividends plus the added accumulations of interest at the rate j . Thus, taking V as the present value of the investment, it is the amount of the unreturned capital over the first year. At the end of the first year the annual dividend, of amount d , is paid. This dividend is made up of two parts: Vi is the interest requirement on the capital at the rate i ; thus $d - Vi$ is the balance placed in the sinking-fund. For the period of the second year the unreturned capital then is, according to the hypothesis taken, $V - (d - Vi)$. At the close of the second year the dividend d is again paid. Allowing interest at the rate i on the unreturned capital, the interest requirement of this second dividend is $Vi - i(d - Vi)$; and the payment into the sinking-fund from the second dividend is the difference between the constant dividend d and this interest requirement, or $d - Vi + i(d - Vi)$. The total amount in the sinking-fund at the close of the second year is the sum of the amount paid into the sinking-fund at the close of the first year plus the interest on this first payment for one year at the rate j , plus the amount paid into the sinking-fund at the close of the second year; the expression for this is $(d - Vi)(1 + j) + (d - Vi)(1 + i)$.

This may be simplified to $(d - Vi)[(1 + j + i) + 1]$.

Thus, the unreturned capital over the third year is $V - (d - Vi)[(1 + i + j) + 1]$.

At the close of the third year the dividend d is again received. The computation for the third year is somewhat lengthy, but it is a matter of simple algebra to

show that the sinking-fund, after the receipt of the third dividend, amounts to

$$(d - Vi)[(1 + i + j)^2 + (1 + i + j) + 1].$$

Similarly, for the fourth year it can be shown that the sinking-fund will amount to the expression

$$(d - Vi)[(1 + i + j)^3 + (1 + i + j)^2 + (1 + i + j) + 1].$$

Obviously, then, for a life of n years, the sinking-fund will have accumulated to the amount of the following expression, which by my hypothesis equals V , or

$$V = (d - Vi)[(1 + i + j)^{n-1} + (1 + i + j)^{n-2} + \dots + (1 + i + j)^3 + (1 + i + j)^2 + (1 + i + j) + 1].$$

The expression within the brackets is again a geometrical series with a ratio $(1 + i + j)$; the sum of this series is equal to $\frac{(1 + i + j)^n - 1}{(1 + i + j) - 1}$, and, substituting this expression for the sum of the series in the above equation, the result is

$$V = (d - Vi) \frac{(1 + i + j)^n - 1}{(1 + i + j) - 1}$$

Solving this equation for V , and grouping the terms according to their order, the result is

$$V = d \frac{(1 + i + j)^n - 1}{(1 + i + j)^n + j}$$

The factor for any particular case can be computed readily from this formula by assuming d to be unity, and putting $(i + j)$ equal to J . The formula then becomes

$$V = \frac{(1 + J)^n - 1}{(1 + J)^n + J}$$

and the value for $(1 + J)^n$ may be taken directly from Table I of Hoskold's tables, pages 31 to 48. The value of the numerator and denominator in the expression may be figured arithmetically, and the computation completed by means of logarithms.

As an example of the application of the new formula, and to exhibit the difference between it and Hoskold's, I give a redemption table constructed from the same case as that taken for the discussion of the Hoskold formula. This is the case of an investment paying an annual dividend of \$1000, the life of the mine to be 10 years, the investor to realize 10% on his capital, and the sinking-fund to be accumulated at 4%; the amount of capital at any period remaining invested in the mine is to be considered as the amount originally put in less the amount accumulated in the sinking-fund. The present value of this investment computed by means of the new formula, is \$6591.37, and the following redemption table has been constructed:

Year	C	d	Ci	$(d - Ci)$	Amount in sinking-fund
1	\$6591.37	\$1000	\$659.14	\$340.86	\$340.86
2	6250.51	1000	625.05	374.95	729.44
3	5861.93	1000	586.19	413.81	1172.42
4	5418.94	1000	541.89	458.11	1677.43
5	4913.93	1000	491.39	508.61	2253.13
6	4338.22	1000	433.82	566.18	2909.44
7	3681.91	1000	368.19	631.81	3657.62
8	2933.72	1000	293.37	706.63	4510.56
9	2080.78	1000	208.08	791.92	5482.90
10	1108.44	1000	110.84	889.16	6591.37

The second column is headed by *C*, which is the amount of capital remaining invested in the mine. The original capital is \$6591.37. At the close of the first year a dividend of \$1000 is received by the investor. As 10% of the capital is to be paid as interest, this absorbs \$659.14 of the dividend. The remainder of the \$1000 dividend, which is \$340.86, is placed in the sinking-fund. During the second year the capital remaining invested is equal to the original \$6591.37 less the amount of the capital now returned, which is \$340.86, leaving \$6250.51. At the close of the second year interest requirements have decreased to \$625.05; and the remainder of the dividend of \$1000, which is \$374.95 is paid into the sinking-fund. The amount in the sinking-fund at the beginning of the third year is now the sum of the first instalment of \$340.86, plus interest on this sum for one year at the rate of 4%, which is \$13.63, plus the amount paid into the sinking-fund at the close of the second year, which was \$374.95; the sum of these three amounts is \$729.44. The capital remaining invested is now the original \$6591.37, less \$729.44, or \$5861.93. The quantities given in the table are found in the same manner for the succeeding years.

Compare the situation at the close of the ninth year in the table constructed from this new formula, with the table constructed upon the Hoskold formula. Under the new formula, at the close of the ninth year the investor has in hand a sinking-fund totalling \$5482.90; hence the capital remaining in the mine is only \$1108.44. Hence, the interest requirement from the ninth dividend is but \$110.84, instead of \$545.58 as called for by the Hoskold formula. It is also shown that, by allowing the investor 10% interest only upon that part of his capital that has not been returned to him, rather than allowing him 10% interest on the amount of his original capital throughout the entire life of the mine, the value of the investment has been increased from \$5455.81 to \$6591.37; the true value of this income is therefore shown to be \$1135.57 greater than the value given by the Hoskold factor. In other words, the Hoskold factor in this particular case is too low by 20.8% of the amount given in the tables.

There is no simple ratio between Hoskold's factors and the factors based on the new formula. The computation of the new factors can be made readily by the method previously outlined. It has seemed worth while to discuss this error in the Hoskold formula at some length; the factors based on this formula have been employed in computing the value of properties worth many millions of dollars, where an error much smaller than the percentage shown in the example taken would of itself be a large sum. I think it is clear that the Hoskold factors are seriously in error, and that the formula which I have deduced is a correct one to employ in the valuation of expected dividends from mining properties.

AN APOPHYSIS is a branch from a vein or dike to which it is attached; an epiphysis is the same but not attached.

Metal Business of Hongkong

Hongkong occupies a rather peculiar position in the metal trade of the Far East. In normal times it is the distributing centre for practically all metals sold in China, the East Indies, Indo-China, the Philippines, Formosa, the South Seas, Siberia, and other parts of the Orient. Because of certain freight and financial advantages it has of late been a distributing centre for tin-plate, steel plates, and other supplies for Japan, imported from Europe and the United States. It is normally the distributing point of Australian lead for that part of the world. On the other hand, China's production of tin, antimony, wolfram, and Siam's wolfram, and in short all other metals produced in the Far East find much of their market in the world through Hongkong. The result is that in times like the present Hongkong's metal market not only follows the ups and downs of other markets with regard to each metal, but by reason of its peculiar position, the influence of silver exchange, and the colony's special relation to the finances of the Far East, its metal market has special features of its own. The great feature of the distributing trade for the past year has been the increasing dependence upon the United States for all supplies and, on the other hand, the increasing demand in the United States for metals produced in the Far East and exported through Hongkong—particularly tin. The chief import has been various forms of iron and steel. The movement in this direction of all the standard forms, but particularly plates, bars, hoop-steel, etc., was strong at the beginning of the year, but in the closing months the effects of export restrictions in the United States were felt.—'Daily Metal Reporter.'

HARDNESS OF ALLOYS may be obtained by additions of relatively small amounts of different metals, as, for example, 1% of tin in copper hardens it 10% on the Brinell scale, and 15% tin increases the hardness 300%. Annealing such bronzes has but little effect on their hardness. Small amounts of zinc harden copper slightly, but with 35% zinc the alloy suddenly becomes very hard. Adding tin or aluminum to brass makes it brittle, unless annealed. Lead and bismuth soften copper, but 15% lead added to tin doubles its hardness, while larger quantities of lead again soften it. Copper and antimony harden zinc, and the same effect may be produced with 0.25% magnesium as with 4% copper. Magnesium is the best hardener for aluminum.

GYPSUM is added as a flux to galena concentrate in the Carnichael-Bradford blast-roasting process of reducing lead ore, as practised in New South Wales. In Germany gypsum is used in reverberatory treatment of leady copper matte. Also in New Caledonia gypsum is employed as the source of sulphur in smelting nickel to form a matte, while the lime in the gypsum supplies the base for fluxing the silicious portion of the gangue.

REVIEW OF MINING

NEW YORK

A. I. M. E. and Enemy Aliens.—A New Hudson Tunnel.—Gold-Leaf Industry.

It has been announced that the American Institute of Mining Engineers will decide during the present month to erase from its roll all honorary, normal, associate, and junior members who are subjects of enemy countries. The Chemists Club is also taking steps toward the same end, and has issued a questionnaire inviting information as to the nationality and sympathies of all its members. The use of the German language has been prohibited in the Club. Sympathizers of alien countries, whether American or alien, are asked to resign forthwith.

The New York State Bridge and Tunnel Commission has reported favorably on the project of connecting Jersey City with Manhattan Island (New York City), by tunnel, and recommends that the work be commenced without delay. The subway will be arranged for foot and vehicular traffic. Estimating an average toll of 30c. for each vehicle and a total of 1,300,000 per year, the project would result in a profit of \$1,500,000 after 20 years of operation. The entrance on the New York side of the Hudson will probably be at the foot of Canal street; and the exit on the New Jersey side at the foot of Twelfth street. Preliminary estimates show that the cost of the tunnel will be \$12,500,000, and that the work will take three years. The subway, when completed, will obviate the danger of coal famines during severe weather when navigation across the Hudson river is hindered by ice. The completion of the work will favor the scheme of arranging for an accumulation of coal on the New Jersey side rather than in New York City, where there is little available space.

The action of the Federal Trade Commission in alleging an illegal combination of the principal gold-leaf manufacturers in the United States, draws attention to a method of increasing the local market value of the beaten product. The evidence indicates that the combine reduced the available supply for the domestic market, and forced up local prices by a scheme which included the exportation and marketing of the gold at a reduced price, the losses from this source being met by the increased profits being made locally. Gold-leaf contains only a small proportion of silver and copper, as the inclusion of other metals decreases its ductility. Nothing is gained by adulteration, as the sheets are sold by surface area and not by weight. Small bars of the alloy are annealed and rolled in steel mills to a ribbon 1/800 inch thick, which is again annealed and cut into squares, 1 by 1 inch. These are placed between vellum and beaten until their total surface measurement is $3\frac{1}{2}$ by $3\frac{1}{2}$ in. The leaf is then placed between gold-beaters skin (an ox membrane) and beaten with a lighter hammer until a leaf about 1/2500 inch thick is obtained. This is trimmed into $3\frac{1}{2}$ -in. squares, and placed between the leaves of a small book, and marketed in this form.

The mining and quarry industry of New York State is detailed in the State Museum Bulletin 196 by D. H. Newland. The important minerals extracted are feldspar, gypsum, graphite, iron ore, salt, limestone, and talc. Molybdenite occurs in the heart of Manhattan Island (New York City), but is covered with buildings.

VICTORIA, BRITISH COLUMBIA

Bounty on Pig-Iron.—New Mining Regulations.—Smelting Charges.

A bounty on pig-iron manufactured in British Columbia is the policy of the Provincial government, according to the Hon. William Sloan, Minister of Mines. He has introduced a bill to the Legislature Assembly providing that on pig-iron manufactured from ore mined in the Province a bounty shall be granted not to exceed \$3 per ton, and that a similar grant, not to exceed \$1.50 per ton, shall be allowed on pig-iron manufactured in the Province from ore mined outside its boundaries. This is considered in western Canada as the most important step taken in years to promote the iron industry in the North-West. It is known that the Province

has immense bodies of unexploited magnetite ore, high in quality. All the authoritative reports available on these deposits have been studied, satisfying the Administration that the iron-ore resources are sufficient to warrant some progressive measure to induce development. The Government has the power to procure diamond-drills and to enter on iron properties held for speculative purposes, and by drilling to estimate the probable tonnage. This will be done, the expense being charged to the property, and, if the owners then take no action, the law will be applied to force them—at least that is the present outlook. An expert in electric smelting is coming from eastern Canada to investigate and submit a report on the best methods of treating these iron ores. All of these investigations should lead to the foundation of pig-iron production in this territory. It is possible that the Dominion government will assist British Columbia in stimulating interest in this matter. A deputation of Victoria and Vancouver citizens is waiting on the Federal authorities at Ottawa urging that action in this direction be taken. It is felt that the Dominion and the Province

should co-operate where the National, and even Imperial, interests are so largely at stake, and those engaged in making these representations feel certain that their efforts will not be in vain. The policy of a bounty on pig-iron is not a new one to Canada. It was adopted by the Dominion government in 1894, when \$2 per ton was offered on pig-iron and steel. In 1897 this was raised to \$3. In 1903 a bounty of \$3 was placed on wire rods, \$3 on structural steel, and the same on rolled plates. These bounties were extended to 1907. Pig-iron manufactured from Canadian ore from 1907 to 1910 was allowed a bounty of \$2.10 in 1907, to 90 cents in 1910. On pig-iron made from foreign ore during the period from 1907 to 1910 there was a bounty graded from \$1.10 in 1907 to 40 cents in 1910. On puddled-iron bars it was placed at \$1.65 in 1907 and graded down year by year until in 1910 it was 60 cents per ton. Bounties also were given on rolled round iron bars. As to the successful working out of this policy it is only necessary to point to the present position of the two companies which derived the greatest advantage, namely, the Nova Scotia Iron & Coal Co. and the Dominion Iron & Steel Company.

Since the above was written the Iron Bounties Act, which binds the Province to give a bounty of \$3 per ton on all pig-iron manufactured from British Columbian ore within its borders, and \$1.50 per ton on all iron manufactured in the Province from foreign ore, is easily the most important mining legislation passed at the recent session of the Provincial Legislature. It went through the House without difficulty, the consensus of opinion being that it was good policy and an opportune move on the part of the Government to encourage the development of the admittedly large deposits of iron in the province. An eastern Canadian iron expert has been engaged by the Government to report on the practicability of reducing the ore by certain furnaces—electric and otherwise. The Minister of Mines stated that none of the known deposits has been worked other than superficially, and few have received any further development than shallow open-cuts, tunnels, or shafts. On Vancouver and Texada islands there is probably 5,000,000 tons. An engineer considers that on the southern coast of the Province there is 630,000 tons of magnetite ore actually exposed, 6,050,000 tons probable, and 10,500,000 tons possible. The magnetite deposits are always replacements of limestone. The iron content is from 50 to 65%, on 600-ton lot averaging 65.7%. Plenty of coke is available for reduction purposes.

['Iron Ore Occurrences in Canada' is the title of a recent bulletin issued by the Department of Mines at Ottawa. This work is in two volumes. A pocket contains 33 large maps. The introduction is by A. H. A. Robinson, while the whole was compiled by E. Lindeman and L. L. Bolton. As a reference for future development of the iron industry the publication is worth securing.—Editor.]

Several changes in the Metalliferous Mines Inspection Act of British Columbia have been made by the Legislature. One provides that all drills used must be attached to a water-spray. This is aimed particularly at a type of drill, which was used here extensively at one time, mostly without such an attachment. Another makes provision for substantial platforms at intervals of not more than 20 ft. in all shafts, whether vertical or a few feet off vertical. Formerly this rule applied only to vertical shafts. A third makes it obligatory for the inspector, after an examination, to post outside the mine a notice describing the condition in which he found the workings. This has been the rule in connection with coal mines, but has not been applied to metal mines in this Province until the present.

The smelting charges recently announced by the Consolidated Mining & Smelting Co., which has the greatest custom works in western Canada, has roused the silver-lead mine operators of British Columbia, who claim that it will mean the closing-down of the majority of their mines. In response

to their petition, the Dominion government has approved of a Commission of Investigation into the schedule and its justification, and the company has expressed its willingness to allow an inspection of its plant and books. Orville R. Whitaker, of Denver, Colorado, has been asked to act in an advisory capacity as an independent expert. The Provincial government will be represented at the inquiry.

MAYER, ARIZONA

New Work in This District.

The Arizona Copper & Mining Corporation is cross-cutting east and west on the 500-ft. level of the new shaft. A shipping grade of chalcopryite and silver ore was cut 30 ft. west of the shaft, this week. Another vein is expected a short distance east of the shaft. This strike is considered important, as it is the first deep mining that has been done in the district within the past 10 years. The mine adjoins the old Hackberry on the north, a producer 20 years ago, and now owned by the Phelps-Dodge Corporation. The Arizona mine is one mile south of the Boggs, also a Phelps-Dodge property. It is in a strong schist belt, being a parallel vein system to the Blue Bell-DeSoto mines one mile west. The directors are considering sinking an additional 500 ft. or develop the present 500-ft. level. No attempt will be made to build a mill until the mine is thoroughly developed. The president of the company is A. L. Davis, and consulting engineer, F. J. Hobson, both of Prescott.

The Mayer Ore Purchasing Co. has leased and overhauled the old Gray Eagle mill one mile east of Mayer, and will operate it as a custom plant. A 100-ton flotation unit has been erected, also two Butchart tables for coarse concentration. As soon as certain electric equipment can be obtained oxidized copper ores will be leached. A custom assay-office has been opened, also sampling works. Ores will be bought for outside reduction works. The new enterprise is in charge of H. A. Wagner, who devised the electrolytic process for which the mill was originally built.

A contract to sink the main shaft at the Copper Mountain Mines Co.'s property on the north end of Copper mountain, has been let to B. H. Bradley and Oscar Holtz of Jerome. It is to be sunk from the 150 to the 600-ft. level. This old shaft was used 25 years ago by the late Isaac Stoddard when he operated the old smelter on the Agua Fria river. S. C. Chaney, mine superintendent of the Arizona Binghamton company, 1½ miles north, is manager for the Copper Mountain company, while the president, Celora Stoddard, is serving in France.

Machinery has been ordered for a 50-ton flotation unit by the Pocahontas Mining Co., two miles south-east of Mayer. The ore is silver-lead, assaying \$20 milling grade, and considerable 100 oz. silver and 20% lead ore for smelting. The mine is well developed.

LEADVILLE, COLORADO

Pyrite and Manganese.

The Leadville district contains some of the greatest deposits of iron pyrite in the United States. This was made clear recently by the arrival here of George C. Venard of Chicago, and F. Morse Smith and E. C. Rafferty of New York, members of the purchasing committee representing the acid manufacturers of the country. They have been appointed to investigate the domestic supply of pyrite, and contract for the purchase of such ores as are found to be up to standard. These men spent a day in the district examining the deposits in many of the big mines, including the Greenback, Yak, Moyer, Mahala, and Wolfstone, where immense bodies have been opened by past development. Following their inspection, they stated that the deposits exposed here are the largest in the United States that are now open to easy extraction. The ores are of standard

grade, and steps will be taken by the committee co-operating with the Government for fixing a price that will make their development profitable to the operators. It is expected that a heavy tonnage of this ore will be produced during the last half of the year.

During April, lessees on the Bohn shaft on Carbonate hill, shipped 500 tons of 36% manganese. This is the best output that has yet been made by manganese producers in this district. The Bohn deposit is regarded as the largest and highest grade manganese in the State.

Leadville went over the top in the Third Liberty Loan, subscribing \$300,000 with a quota of \$233,000. More than 2000 subscribers applied for bonds.

Cloverdale, California

Operations Along the Quicksilver Belt.

Owing to the present prices and demand for quicksilver, production of the Sonoma County area promises this year to greatly exceed all former yields. This zone, roughly outlined by proved mines, is known to extend from a point 20 miles east of Cloverdale to the Sulphur Bank mine in Lake county, approximating 40 miles. Mercury is now being produced by the Cloverdale, Culver-Baer, Western Mineral, Rattlesnake, Socrates, Big Injun, Big Chief, Helen, Mirabel, Oat Hill, Aetna, and Sulphur Bank mines, and others. The steady price for the metal has given confidence to these companies. At all of these mines development is under way. The Socrates mine is probably the most important. It was re-opened May 1, after being closed for 60 days on account of a re-organization. It is predicted that during the summer it will produce more than ever. William Navas, foreman of the Socrates mine, stated that the company proposes at once to drive an adit 2100 ft. on No. 6 level, to cut the orebody at a depth of 400 ft. below present workings. At the plant of the Western Minerals Co., 2½ miles west of Geyser Springs, Andrew Rocca Jr., superintendent, and 30 men are employed, handling ore that averages 10%. Production at this mine is said to be about 125 flasks per month. Rocca is also superintendent of the Helen mine, farther east. Labor conditions are causing some uneasiness in the district. Charles Humbert, president of the Culver-Baer mine, 19 miles east of Cloverdale, stated that this property is now capable of producing, by running the two furnaces to full capacity, from 20 to 80 flasks per month, grade of ore determining output. This statement was qualified, however, by an explanation that wages of \$3.50 to \$4 per day were no longer attractive. On account of labor conditions, he said it was becoming increasingly difficult to keep production up to normal.

Sudbury, Ontario

International Nickel Co.: Merger and Taxation.

The International Nickel Co. of Canada, a subsidiary of the International Nickel Co. of New Jersey, is arranging a merger with the Canadian Copper Co., another subsidiary of the same concern, operating the company's mines at Sudbury, with a capital of \$50,000,000. The Canadian company has a capital of \$5,000,000. It was organized in 1916 to carry out the arrangement made by the parent company with the Dominion government to refine in Canada all the nickel required for the British Empire. In pursuance of this agreement it is now constructing a large refinery at Port Colborne, Ontario. The large increase in capital indicates that operations at the Canadian refinery will be on a much more extensive scale than originally contemplated, which is easily accounted for by present conditions. In addition to the heavy taxation imposed by the Provincial government, amounting to \$750,000 per annum, the New Jersey company is subject to war taxes on its business in the United States, and by transferring its operations to the

Canadian side of the border, it can escape the double tax. As the Port Colborne refinery is being built on the unit system, additional capacity can be made as required. The view in official circles is that operations of the company will be gradually withdrawn from the United States and centred in Ontario. The Canadian Copper Co. has appealed in vain to the Dominion government against the Ontario tax, and asked for its disallowance. It was contended that under the method adopted for assessing the profits liable to taxation, profits made in the refining process carried on in the United States were included; also that the law discriminated unfairly between the International and the Mond Nickel companies, the latter being allowed to deduct from its taxes the amount paid in Great Britain where its ore was refined, whereas no allowance was made to the International on account of American taxation. These objections were overruled, and the appeal dismissed.

Boston Creek.—The machinery for the new mill of the Patricia Syndicate has arrived on the property, and is being installed. It has a capacity of between 50 and 60 tons per day. Charles O'Connell, formerly manager of the Tough-Oakes, is manager and part owner.

LEAD, SOUTH DAKOTA

Gold, Lithia, and Mica Mining.

Lead.—The annual report of the State Inspector of Mines, Otto Ellerman, covering the year 1917, has been published. Mining was quieter than for a number of years. Regular producers continued on a normal basis. Bullion extracted was only \$62,348 short of 1916. Copper, gypsum, lead, lithia, and tungsten ores showed increases, and are expected to do so in 1918. There were 2757 men employed at all mines, a decrease of 312. There were 7 fatal accidents. Operations of the operating companies are briefly described. Production was \$7,501,234 gold and silver, \$247,096 tungsten, \$47,500 gypsum, \$25,620 lithia, \$25,268 coal, \$9259 mica, \$8275 tin, \$6695 lead, \$1887 copper, and \$1670 manganese. Tin decreased \$6000 and tungsten \$140,000.

The Bismarck gold mine at Flatiron has been leased to Edward Manion, formerly superintendent of the Wasp No. 2. The property is equipped with a 200-ton cyanide mill, which will be placed in commission as soon as development warrants it. The ground adjoins the Wasp No. 2 on the north, and has been operated intermittently for the past few years.

Deadwood.—After continuous work for over 35 years the Golden Reward Consolidated Gold Mining & Milling Co. has suspended work. Experiments on the blue ores will be continued, but the main work has been stopped. This is one of the larger producers in the district, and the reason for closing is due to advanced costs, the ore not being rich enough to be profitably treated. Development of the Cutting property continues. Two drifts are being extended to cut the ore. The lower of these is in over 200 ft. It is expected that the ore developed at a higher level will be cut within a short distance. An installation of power machinery is under consideration.

Keystone.—The Ingersoll mine has been leased to A. T. Roos and associates, who will place it in shape for shipping lithia ore.

Rhodes and Woods are shipping mica from the George Palmer property near Spokane. Several carloads have already been shipped to the Eastern market.

The Dakota Continental Copper Co. is loading ore for the smelter. It is all taken from surface workings at the Calumet mine. Work at the Golden Summit, near Hill City, which this company has been developing for over a year, has been suspended.

The Rheinbold and Standard Essence companies continue regular shipments of lithia ores. In addition to this the Rheinbold is marketing some mica.

THE MINING SUMMARY

ALASKA

Juneau.—Alaska Gastineau in April treated 125,435 tons of ore assaying \$1.148 per ton. Extraction was 81.45%. This is a reduction of nearly 25,000 tons from the March output.

Kennecott.—The Kennecott Copper Corporation is to acquire control of the Mother Lode Mines Co. through a new company with 250,000 shares of no par value, the Kennecott to hold the majority. Approximately \$1,000,000 will be paid the Mother Lode company, which has been unable to finance development.

ARIZONA

Kingman.—Material for the McCracken Silver Lead company's 100-ton mill is arriving and construction started.

Ore assaying \$50 per ton has been opened on 400-ft. level of the Banner mine. This company is erecting a new compressor and other machinery.

The Mohave Molybdenum Co. has been organized to work claims in the Wallapai mountains.

Jerome.—At request of both sides, the hearing for the claim for \$250,000, freight overcharge to the United Verde Extension by the railroads, has been postponed indefinitely.

Oatman.—The Tom Reed Gold Mines Co. reports as follows for the past two years:

	1917	1916
Ore treated, tons	81,656	46,170
Value per ton	\$7.60	\$11.03
Extraction, per cent.	97
Cost of mining	\$2.20	\$2.65
Cost of milling	\$2.04	\$2.09
Profit	\$90,000	\$170,000
Reserves, tons	80,000

The new orebody in the Bald Eagle claim will be ready for milling by July. W. B. Phelps is superintendent.

Nogales.—The Arizona European Mining Co., which commenced operations last fall, is making good progress. In the old shaft 460 ft. of sinking and other work has been done. Six cars of ore yielded 14 lb. copper and 4 oz. silver per ton. A new shaft has also been sunk 115 ft. and some driving done.

It is reported that high-grade copper-sulphide ore has been opened in the west drift of the 40-ft. level of the old Hickory mine. Molybdenite has also been found on two levels, claimed to carry as high as 8% MoS₂.

Patagonia.—The Hilltop mine is making excellent progress in the lower adit, where 50 men are employed.

The Nippers mine is employing a small force on development under H. W. Loomis.

The Blue Eagle mine is to start work immediately. F. A. Shaw has interested New York capital in the mine.

Word has been received that work will start on the Hardshell mine in a few days, M. Saunders, who has a lease and bond on it, having secured financial backing.

Ray.—The dry-concentrating plant of the U. S. Vanadium Co. has been completed. Preliminary trials, it is reported, indicate that the mill will be a success.

Rodeo.—The King Copper mine is 12 miles north-west of

Rodeo on the Southern Pacific railroad. Ore carries lead, silver, and copper. The power-house encloses a 200-hp. Webber distillate engine, 80-kw. Westinghouse electric generator, 800-ft. Ingersoll-Rand compressor, and other plant. There was recently installed a Westinghouse generator and switchboard, also a 10,000-gal. fuel-oil tank. The concentrating mill is nearly complete, and when all units are finished they will have a capacity of 150 tons per day. David Snyder of Denver is president.

CALIFORNIA

At the public meeting of gold-dredge men, held on May 7 at the offices of the Industrial Accident Commission, as mentioned in this journal of May 11, to discuss the amended tentative safety rules for dredges, attention was mainly directed to first-aid training and electric safeguards, in so far as they were more easily complied with by the larger companies operating a number of boats than by companies operating one or two boats in remote parts of the State. The rules as they have been amended will come up for discussion at a meeting of the dredge operators to be held at Lodi on May 16, 1918. This meeting is expected to develop more accurately the feeling of operators at this time of high costs of supplies and low efficiency of labor, also whether the rules will create undue expense to those boats operating on a small margin of profit. The final meeting of the committee for considering the rules before presenting them to the Commission for adoption will be held on June 20 at 10 a.m., at its offices at San Francisco.

Bay Point.—The Pacific Electric Metals Co. on May 13 started its new 40-ton ferro-manganese plant here.

Kennett.—The Mammoth Copper Co. has sold the 4½-mile Quartz Hill railroad for junk. The road was built in 1903 to haul silicious rock from the Quartz Hill mine to the Southern Pacific line at Cuervo for shipment to the smelter as flux. Three hundred tons were shipped in seven years. Now the company gets flux elsewhere to better advantage.

Livermore.—J. E. Stock and J. J. Cummings Jr., of the Western Magnesite Co., have been ordered by the Master in Chancery at San Francisco to pay the company \$26,883.07 for magnesite mined and sold, on the grounds that the mining claims were obtained by fraud. The defendants contended that they had spent \$60,000 at the property and were entitled to expenses; this was denied them. The mine is 40 miles south of Livermore, which is the nearest rail point.

Lewiston.—The Trinity Star Dredging Co. has suspended construction of its boat, owing to war conditions and the shortage of labor.

Redding.—Three carloads of machinery have been received at Redding by the American Gold Dredging Co. This is from a dismantled boat in the Oroville district.

Trinity Center.—The Estabrook Gold Dredging Co. has been unable to raise its dredge, which sank about a month ago, and has abandoned it. A new one is being built.

After closing down since last October the Bonanza King mine is to be re-opened. The compressor has been repaired, power-line overhauled, and considerable re-timbering done.

COLORADO

Cripple Creek.—Residue dumps at the Golden Cycle and Portland are reported to contain from 8 to 10% potash, so an experimental plant costing \$50,000 is to be erected to devise a process of extraction.

A U. S. Bureau of Mines safety-car is soon to visit this district.

The Cripple Creek Deep Leasing Co.'s lease on the Jerry Johnson mine has expired. The bottom, or 950-ft. level, has been leased to P. H. Denham.

Leadville.—The Greenback Mining Co.'s management has passed from Patrick Mulrooney to A. K. McDaniel, with H. C. Watson in charge of the mine. Pumps and air-connections in the 1350-ft. shaft are to be overhauled, also surface machinery. Ore opened is considerable, but low grade; and a third of the ground has not been explored. Most of the ore consists of pyrite, high in sulphur with a little silver, estimates placing the quantity at 300,000 tons.

IDAHO

Stampmill.—This new silver district is on the western slope of the Owyhee range, 5 to 7 miles south of Silver City in Owyhee county. Little deep work has been done so far.

PART OF IDAHO, SHOWING SITUATION OF STAMPMILL DISTRICT.

The district was prospected in the early sixties. A number of mines are being worked and several mills are contemplated, the Owyhee Silver Mining Co. being one of them.

Wallace.—The Friend Mining Co. in the Beaver district is opening lead-silver-zinc ore, is repairing the wagon-road, and contemplates ordering a crusher, ball-mill, table, and flotation plant. From 60 to 100 tons of concentrate is expected monthly. William Schierding is manager.

We are informed that the Grasselli Chemical Co., under a contract with the Success Mining Co., received the entire output of zinc ore and zinc concentrate, and that no dispute has ever arisen over the proper settlements for shipments. The new management of the Success company requested a modification of this contract in the direction of a higher price, which could not be granted on account of prevailing conditions in the zinc industry.

MISSOURI

Joplin.—Production of the region last week was 8088 tons of blende, 338 tons calamine, and 1519 tons lead, averaging \$42, \$30, and \$50 per ton respectively. Total value was \$494,923, making \$8,555,357 for 18 weeks. Oklahoma contributed \$297,680 and Kansas \$84,861. About 1400 tons of high-grade blende was sold at \$75 per ton, the new basis for this product, as arranged with the Government.

MONTANA

Butte.—At the Black Rock shaft of the Butte & Superior a skip fell from the surface to 1200-ft. level, damaging one

compartment considerably. This resulted in a shut-down for several days.

Helena.—The A. S. & R. Co. has raised wages 25c. per day to its East Helena smelter employees. The minimum is now \$3.40 per shift.

Polaris.—The Silver Fissure Mining Co. is starting work on a 50-ton mill, involving chloridizing roasting and hypsulphite leaching of silver ore.

NEVADA

Bullfrog.—This centre is reported to be more active than for some years. Liberty Loan subscriptions totaled \$17,000, a third more than the quota.

Cuprite.—After being closed for 10 years the sulphur deposits here, 15 miles from Goldfield, are to be re-opened. James Forman of Tonopah and A. S. Putney of Manhattan have been examining the district.

Manhattan.—In the apex suit of White Caps v. Morning Glory, Judge M. Averill on May 8 upheld every contention of the plaintiff.

The Commercial Mining & Milling Co. has leased the Big Pine mill. This is a combination ball and pebble mill. A large quantity of dump ore, assaying from \$1.25 to \$1.90 per ton will be treated.

Rochester.—Net profit of Rochester Mines Co. for first quarter of 1918 was \$62,988, against \$46,934 in the last period of 1917.

Sodaville.—This tungsten district is having a revival, and Beck & Noonan, Edward Wagner, Bernady Tungsten Mines, Mark Young, and the Tungsten & Gold Telluride companies are busy developing ore.

Tonopah.—The first survey of a railway to the Gold Mountain district is finished, but two others are to be made to try better grades. In the six miles will be some deep cuts, and a rise of 800 ft., equal to a 3% grade.

OKLAHOMA

Picher.—The zinc-lead region last week yielded 5118 tons of blende and 1112 tons of lead, valued at \$297,680.

UTAH

Alta.—The Little Cottonwood Transportation Co.'s new freight schedule means a reduction of 50% on haulage charges from this district to the main line.

Dugway.—The Lucky Star Copper Co., which is shipping a little ore, may construct a small mill.

Park City.—Ore and concentrate production of this district in April totaled \$392 tons, compared with 11,500 tons in March. Ontario led with 2800 tons, followed by Judge with 2173 tons, Silver King Coalition with 1387 tons; Silver King Con. with 1072, and Daly West with 550 tons.

Tintic.—Ore and concentrate output of this district in April totaled 30,000 tons from 35 producers.

CANADA

British Columbia

Silverton.—The Galena Farm Mining Co. is shipping lead and zinc concentrates. The latter carries 41% metal. On 100-ft. level the ore-shoot is 300 ft. long. There are 70 men engaged.

Trail.—The former schedule for payments on lead ore received at the smelter were restored on May 1.

Ore received at the smelter here during the third week of April totaled 7729 tons. Le Roi contributed 2679 tons, Sullivan 1858 tons, and Centre Star 1317 tons. One hundred and four tons came from the Mandy mine, Pas district, Manitoba.

Ontario

Kirkland Lake.—The Ontario-Kirkland Gold Mines has \$50,000 and is to start work on its Hurd claims near the Wright-Hargreaves.

Lightning River District.—Assessment work on claims in this area, recently stopped on account of possible damage to the Abitibi Power & Paper Co.'s property, is to be resumed.

Porcupine.—McIntyre-Porcupine mine is in splendid condition. Profits are equal to 25% on capital. Main drift on 1000-ft. level from McIntyre claim through Extension and into Jupiter will soon be finished. It will be about half-mile long. Electric locomotives will haul ore-cars to main shaft. Mill has a capacity of 600 tons daily.

Yukon

Dawson.—Ten miles above the Yukon Gold Co.'s powerhouse, on the Little Twelvemile, D. B. Cole and others have opened a promising lead-silver deposit. In spite of difficulties and 38° below zero, the owners mined 40 tons of ore, which was sorted to 6 tons worth \$150 per ton. About 18 claims have been staked in the vicinity.

The ice of the Yukon broke on May 11, doing considerable damage at Dawson.

Tagish.—Venus mine of J. L. Harper, formerly of Republic, Washington, has a new mill dressing lead-silver-gold ore. T. B. Landers is in charge.

MEXICO

Chihuahua and Sonora

Report of the Mines Company of America, operating mines in both of the above States, has been issued. Owing to unsettled conditions in northern Mexico no ore was treated last year. There was an operating loss of \$92,138 for 1917. The surplus of \$975,154 at the end of 1916 was reduced to \$642,690, by depreciation, loss, taxes, etc. Reserves in the properties are as under, gold being calculated at \$20 and silver at 90c. per ounce:

Company and situation	Tons	Total value
Dolores Mines Co., Chihuahua.....	149,223	\$2,900,651
Chihuahua-Esperanza Gold Mining Co., Chihuahua	2,550	52,530
Consuelo Mining, Milling & Power Co., Chihuahua		
El Rayo Mines Co., Chihuahua.....	78,538	1,068,289
Creston-Colorada Co., Sonora.....	190,350	1,220,080
La Dura Mill & Mining Co., Sonora..	16,015	1,265,125
Total	459,676	\$6,506,675

Normally these mines employ 1500 people. The directors are considering resumption of operations.

Guanajuato

Guanajuato.—The Guanajuato Reduction & Mines Co. reports that full capacity was reached late in April 1918. The American staff left the mine in April 1916, but returned in July 1917, when the political outlook and cyanide supply looked better. Freight, supplies, taxes, etc., were much higher, but silver was also higher and it was expensive to maintain the property ready for operation. In December, 80 of the 160 stamps started crushing ore, gradually dropping more until now all are in operation. To secure supplies an arrangement was made with one of the companies operating privately-controlled trains under contract with the National lines. Expenditure in Mexico during 11 non-operating months of 1917 was \$70,437. Tests by flotation were not favorable, but are being continued. The general manager, H. P. Smith, reports that a re-calculation of reserves in the mines gives the following:

Ore	Tons	Silver, gm. per ton	Gold, gm. per ton
Blocked out	186,180	253	2.87
Probable	146,400	256	2.78
Dumps	481,966	165	1.40
Total and averages.....	814,546	202*	1.98†

* 7 oz. per ton. † 0.06 oz. per ton.

The cash balance at beginning of 1917 was \$243,825, and at end of year \$58,021. The company has Liberty Bonds worth \$5000.

Hidalgo

Pachuca.—The report of the U. S. Smelting, Refining & Mining Co. for 1917 has the following to say regarding operations by its subsidiary, the Compania de Real del Monte y Pachuca:

In Mexico, during the first part of the year, operations were still hampered by difficulties mentioned in the last annual report. Only one mill could operate, and that at only part capacity. Operations continued to be conducted at considerable loss until June. As anticipated, the second mill commenced to operate during the second quarter and from July to the end of the year both mills were operating, and for the last six months averaged 54,600 tons monthly, which was over their rated capacity of 50,000 tons. Substantial profits were made from June to the end of the year, and still continue. While wages have increased at the Mexican property, labor efficiency there improved to the extent that practically offsets such increase, but the increased cost of cyanide, dynamite, timber, and other materials purchased in the United States and transported to Mexico under extraordinary difficulties and heavy expense, more than offset the increased price of silver realized during the year. None of the ore from the new vein was mined and treated during that period, except what came from development work and a small amount of stope preparation. At one mill an additional capacity of 9000 tons monthly is being completed and put into operation during the first quarter of 1918. At the other mill, the installation of an additional capacity of 9000 tons monthly is being delayed by various difficulties, but it is now expected that this will go into operation during the first quarter of 1918. The new mill of 15,000 tons capacity contemplated for treatment of ore from the new vein is being delayed for various reasons, some of which are: first, that while the ore thus far developed in this new vein is several times richer (and has eight or more times the profit-value per ton) than the average ore treated during the year, and now being treated; second, it is somewhat more complex, and much time has been required to carry on experiments necessary to ensure the best method of treatment; and, third, almost prohibitive difficulties and high costs of obtaining and transporting materials for this proposed new construction. On account of this delay, plans are under consideration for immediate commencement of mining some of the ore from this new vein, and treating it in the present mills. This will displace and postpone the treatment of some of the lower grades of ore now being treated, but should add materially to earnings for Mexico for the balance of the year 1918. Another feature which should help to increase earnings is that developments in the new vein have continued to be so satisfactory that taken together with results in some of the company's other mines, there is enough ore blocked out and in sight to warrant discontinuing developments in some inactive mines and to reduce prospecting and development expense in all our Mexican mines.

Sonora

Nacozari.—El Canario Copper Co., controlled by the Canario Copper Co., is operating El Canario, 15 miles east, and the Lillie and Lillie Segunda mines, 3 miles west of

Nacoziari. El Canario adjoins La Caridad of the Moctezuma Copper Co., and ore carries copper in the form of enargite. A 300-ton flotation plant is contemplated. The Lillie has been shipping intermittently, but in about 60 days will be producing a carload of 20% ore daily. This also carries a fair quantity of silver. The ore is said to be desirable for smelting, as it contains 10% lime. The Lillie Segunda has considerable prospects. James P. Harvey is president of the company, residing here, and S. H. Pyle is superintendent.

The San Nicolas Leasing Company, with properties situated about 15 miles west of Cumpas, has just completed construction of a 50-ton flotation mill, expected to be in operation early this month. The plant is owned by six Douglas men who have secured a three-year lease on some valuable silver properties, the ores of which will be concentrated in the new mill. It is expected that about two tons of concentrate will be milled daily, shipments to be made to smelter at El Paso. W. R. Maycumber is in charge of 30 to 35 men.

Tamaulipas

Nuevo Laredo.—A Consular Report states that there are several promising mining regions contiguous to this centre, although there is no important activity at present. There are also indications of oil. In the vicinity of Guerrero, a

PART OF TEXAS AND PART OF MEXICO.

village 85 miles down the river from Nuevo Laredo, there is a coal deposit. This property is still undeveloped, owing to absence of railroad facilities. The zinc and lead deposits are in the Villadama mountains, and along the railroad between the towns of Lampazos, Guadalupe, and Villadama. These properties are now being worked and the product exported to the United States.

Exports through this port to the United States for the last two years are as under:

Metal	1917	1916
Copper, pounds	349,751	279,399
Gold, value		\$96,001
Lead, tons	6,712	5,052
Quicksilver, pounds	3,300	
Silver, ounces	820,234	979,058
Tin, pounds	3,740	5,400
Zinc, tons		561
Zinc ore, tons	44,245	72,474

Nuevo Laredo derives its importance from the fact that it is the gateway to Mexico and the seat of the principal Mexican 'port of entry' on the national boundary. It is a transshipping centre of great importance to the United States and Mexico.

PERU

La Fundicion.—Cerro de Pasco produced 5,952,000 lb. of copper during April.

Morococha.—The Morococha Mining Co. will erect a smaller mill similar in general arrangement to the addition to be made to the mill at Cerro de Pasco. The products will be sent to the smelters of the Cerro de Pasco company at La Fundicion.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

Frank L. Sizer is in eastern Oregon.

John W. Finch was at Yokohama recently.

J. A. Martin has left Alaska and is now at Cleveland, Ohio.

The partnership of **Hills & Willis** has been discontinued.

C. H. Jones has returned from Siberia and is now at St. Louis.

E. P. Mathewson is now residing at Santa Barbara, California.

W. E. Sanders, formerly at Butte, is now living at Pasadena, California.

J. Parke Channing has been in San Francisco, on his way to Miami, Arizona.

D'Arcy Weatherbe sailed on the 'Tenyo Maru' for Yokohama, on his way to Manchuria.

John D. Hoffmann sailed from San Francisco on May 14, for Yokohama, on his way to China.

Murray Coleman has resigned as superintendent for the Atolia Mining Co., and is proceeding to Japan.

L. C. Uren, assistant professor of mining at the University of California, is doing work in the oil department of the Fuel Administration.

David H. Collier left for Namtu, Burma, India, on May 14, to take a position in the engineering department of the Burma Corporation.

Alfred Tellam has been appointed metallurgical engineer for the Hardinge Conical Mill Co., with headquarters at Salt Lake City and Denver.

H. W. Morse, of the Western Precipitation Co., has been engaged as chief chemical engineer to the American Trona Corporation in place of C. P. Grimwood.

E. W. Bullard, safety engineer with E. D. Bullard, is now second Lieutenant in the 347th Regiment of Field Artillery, Camp Lewis, Washington. He was married to Miss Esther Bull on April 4.

Obituary

Lucius S. Pierce, inventor of the gold amalgamator bearing his name, died at Denver, Colorado, three weeks ago.

Percy Le Roy Fearn was injured in an automobile accident at El Paso on April 15 and died the next day. He graduated from the Columbia School of Mines in 1887. His son, Hewitt, also a graduate from Columbia, and now in the Regular Army, came from camp near Portland, Oregon, to be present at the funeral. At one time he was in partnership with Messrs. Olcott and Corning in New York. Recently he was operating the Lady Franklin mine, at Kings-ton, New Mexico. The news of his death will be a shock to many members of the profession, by whom he was regarded as an honored friend and a skillful engineer.

Edward Hale Perry, Lieutenant in the 6th Engineers, has been killed while at the front in Picardy. He was born in 1887; he graduated from Harvard College in 1909, and from the Harvard Mining (the Lawrence Scientific) School in 1912. Until 1915 he worked, in the laboratory and in the field, at the problem of secondary enrichment, and from 1915 to 1917 he was associated with Augustus Locke in the geologic examination of mines. He made a special study of rock alteration in connection with ore deposits, and had begun to make good use of it in a practical way. He was a man of imagination and energy, promising to be a mining geologist of the first rank. The early, but glorious, end to so promising a career will sadden many besides his personal friends.

THE METAL MARKET

METAL PRICES

San Francisco, May 14

Aluminum-dust, large and small lots, cents per lb.	65-70
Antimony (wholesale), cents per pound.	15
Copper, electrolytic, cents per pound, in carload lots.	23 1/2
Copper, electrolytic, cents per pound, in small quantities.	24 1/2
Lead, pig, cents per pound.	7 1/4-8 1/4
Platinum, pure and with 10% iridium, per ounce	\$108-\$116
Quicksilver, per flask of 75 lb.	\$110
Spelter, cents per pound.	9 1/4
Zinc-dust, cents per pound.	17 1/2

ORE PRICES

May 14

Antimony, 45% metal, f.o.b. California, per unit	\$1.10
Chrome, 38% and over, California, per unit	\$1.25-\$1.50
Magnetite, crude, California, per ton (nominal price)	\$7.00-\$8.00
Manganese, 40 to 50% Mn, Hazen, Nevada, cents per unit	92-110
Manganese, 45% New York, per unit	\$1.20
Molybdenite, lb., 85% MoS ₂	\$1.80
Pyrite, domestic, New York, cents per unit of sulphur	28
Tungsten, 60% W ₂ O, California, per unit	\$24

Carnotite (radium-bearing) ore: the mining and concentration of these ores is fully described in Bull. 103 of the U. S. Bureau of Mines, just to hand.

EASTERN METAL MARKET

(By wire from New York)

May 13—Copper is strong though unchanged. Lead is quiet and steady. Spelter is firm and higher. Platinum is nominal up to \$150.

SILVER

Below are given official (not Government) quotations, in cents per ounce of silver 999 fine. In order to make prompt settlements with smelters and others, producers allow a discount from the Government price of \$1, hence the lower price. The equivalent of dollar silver (1000 fine) in British currency is 46.63 pence per ounce (925 fine), calculated at the current rate of exchange.

Although silver in New York averaged \$141c. per oz. in 1917, the Nipissing Mining Co. received \$319c. net at Cobalt, Ontario. There was 3,708,892 oz. sold on company account.

Silver exports from San Francisco to the Orient during April amounted to \$7,206,637. Early in May a very large shipment was made, but figures are not available. It is reported that \$13,000,000 was to be sent to the Orient on about May 14.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound. In February 1918 the market for high-grade standard grade A spelter at 12c. per lb. for itself and the open market. This grade constitutes only a small proportion of the total output. Lower grades can make their own prices as usual. Sheet-zinc is fixed at 15c. per pound.

High-grade zinc-ore producers in the Missouri-Kansas-Oklahoma region have arranged with the Government that present requirements of this ore for sheet-zinc makers are to be allocated by a committee appointed by the War Industries Board. The price of \$75 per ton is suggested. F. B. Butler, O. F. Brinton, and John Hoffman, all of Joplin, were selected to serve as the allocating committee to decide on the quantity to be supplied by each producer.

COPPER

On September 21, 1917, the Government fixed copper prices at 23.50c. per lb. for large lots, and 24.67c. for small lots, effective until June 1, 1918. Quotations in cents per pound are as under:

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. The Government is taking 40% of the United States quicksilver output, paying therefor \$105 per flask. Outside of this business the competitive market can make any price as usual. Prices, in dollars per flask of 75 pounds:

Date	Average week ending	Apr. 2	1916	1917	1918
Apr. 16	115.00	30	115.00	115.00	115.00

ORES

Antimony: There have been no developments and prices are unchanged. Manganese: March imports were only 19,300 long tons, the lowest in over two years. This is perhaps indicative of the extent to which the Government is restricting shipments from Brazil; the situation is not encouraging. The extent of the falling-off in March is shown by the fact that the January and February receipts averaged 61,018 tons each, with the 1917 average at 52,438 tons per month. Molybdenite: More interest is displayed, but it has not yet developed into much buying. Quotations are unchanged at \$1.80 per pound. Tungsten: Considerable activity is reported, with sales of various grades at the ruling price of \$24 and \$24.50 for high-grade ores and of \$20 for others. Ferro-tungsten is unchanged at \$2.25 to \$2.35 per lb. of contained tungsten.

Eastern Metal Market

New York, May 8.

In general the markets are all quiet, though a little more activity is displayed in one or two, as well as a better tone.

Copper is in strong demand for May delivery, but the situation as a whole awaits price-fixing discussions in Washington.

Tin prices continue to soar to still higher record levels, with business of any account impossible.

Lead is quiet and lower.

Zinc is firmer, higher, and displays a better tone.

Antimony is more active.

In the steel trades buying for general use has stopped short, and the industry is devoting itself entirely to the big task set for it by the War Industries Board. There is still the belief that 60 days' concentration on war needs, and the appeal this may make to workmen to increase output, will relieve the situation in no small degree by July 1. The April pig-iron statistics bear favorably on the war steel situation, showing the largest month's output since May 1917. At 3,288,211 tons in the 30 days of April, production was at the rate of 109,607 tons per day, against 3,213,091 tons in March, or 103,648 tons per day, a daily gain of nearly 6000 tons. Of 2,200,000 tons of shell steel already allocated for 1918, shipments thus far amount to 1,500,000 tons. The year's orders on shell account are put at 5,000,000 tons.

COPPER

It was generally supposed that the meeting in Washington May 1 was between copper producers and the War Industries Board or its representatives, but it is now learned on good authority that such was not the case. The meeting was one for the discussion of the refining cost problem and was attended by only the representatives of the refiners. No details are obtainable as to what transpired or as to the attitude of the Government. This will develop later. It is known that refiners presented the situation from their point of view as to the mounting costs for refining, which are no doubt realities of a serious nature, and which are gradually eating into the profits because compensation for refining is based on the old contracts. The meeting will be continued on May 22, at which the copper producers will present their side of the case. The Government will then have all the facts before it on which to base a decision as to an advance over the 23.50c. copper price, which holds until June 1. No reduction is expected. Some trade-opinion is to the effect that, if the refining charge is increased, an advance in the other price will be necessary. Otherwise many small producers will not be able to pay a higher refining cost and make both ends meet. One instance is cited of a small producer who, under present conditions, turns out copper at 22.75c. per lb., leaving a profit of only 1c. Another disturbing factor is the movement among copper laborers and miners for an advance in wages. Their representatives are soon to petition the Government for an advance claimed as necessary because of the higher cost of living. Demands of copper for May delivery are very large for Allied and American war needs, and there is some doubt whether these can be met in full. The price for copper in the jobbing market is 24.67½c. per lb. and the demand is fair but supplies none too adequate.

TIN

The situation goes from bad to worse, and there seems to be no relief in sight. Good news is meager. It seems probable now that sailings from the Dutch East Indies will be permitted, which will relieve the tension somewhat. In

England the tin market has virtually been taken control of by the Government. To buy or sell tin there now permission must be obtained from the Government, and under these regulations the sales of a few parcels have been permitted to consumers in the United States for shipment from the Far East. The quantity involved, however, is small. In the last week little business has been transacted, and in fact but little could be done. Under present conditions no large business is possible. Prices have also continued to rise here and in foreign markets until unheard of heights have been reached. For spot tin of any grade as high as \$1 to \$1.05 would be paid were the metal obtainable, and for future delivery from the Far East for any position from 95 to 98c. is the quotation. In London a similar situation prevails. Spot Straits has again advanced to £20 per ton in the week to £381. Arrivals at Atlantic ports to May 6 inclusive have been 275 tons. In April the deliveries of tin from Pacific ports to the Eastern seaboard were 4495 tons, which, with the 550 tons arrived at Atlantic ports and the 64 in stock and landing on April 30, makes the total April receipts 5109 tons.

LEAD

Conditions are practically unchanged from those obtaining for the last few weeks, and the market is quiet. In fact the long dullness is regarded as queer because usually at this time of the year there is pronounced activity. Many large sellers continue to have no lead to offer, or else they do not care to meet the present prices. But there are a few sellers who continue to make offerings which seem to be more than the market can absorb. This has, of course, resulted in a lower level of prices, so that yesterday lead was quoted at 6.42½c. St. Louis, or 6.62½c., New York, for early delivery. There is decided lack of interest, with the supply greater than the demand. The American Smelting & Refining Co. still maintains its price at 7c., New York, to the surprise of many.

ZINC

The market has taken a turn for the better, and the tone is more cheerful. One of the main reasons for this is the understanding that the Government has made large purchases of high-grade and grade-C zinc and is to make still more. It is expected even that these purchases will be such that some prime Western or similar grades will have to be re-distilled to meet the Government's needs. Another factor is the disinclination of some large producer to sell for future or even for nearly delivery at the present price-levels, at least in quantity. The higher price agreements for top-grade ore in the Joplin district, by which a \$75 price is proposed, is also a bullish factor. Demand is not large, but there is more interest displayed. The market may be quoted for early and May delivery at 6.87½c. to 7c., St. Louis, or 7.12½ to 7.25c., New York, for prime Western with June delivery not less than 7c., St. Louis, or 7.25c., New York. For grade A the maximum price is 12c., and for sheet zinc, 15c. per lb. base.

ANTIMONY

Because of reported buying by the Government and by some others, the market has been more active recently, and is firmer at 13 to 13.25c., New York, duty paid, for spot and early delivery of Chinese and Japanese grades.

ALUMINUM

For No. 1 virgin metal, 98 to 99% pure, Government prices control the market. They range from 32 to 32.20c. per lb. in lots of 50 tons down to 1 ton.

Company Reports

Some silver producers at Cobalt, Ontario:

CROWN-RESERVE MINING CO., LTD.

Property: silver mines at Cobalt, control of the Porcupine Crown gold mine at Porcupine, and control of the Reward gold mine in Inyo county, California.

Operating Official: Harry Steward, general manager, since April 1918, Samuel Cohen previously.

Financial Statement: income from silver, etc., in 1917 was \$265,155, less \$182,582 for operation, leaving a profit of \$82,573. Balance from 1916 was \$773,587, and that carried to 1918 was \$781,765. Receipts from investments, etc., were \$73,920.

Dividends: none was paid last year, so the total remains at \$6,190,849.

Development: total underground work in the Crown Reserve mine was 2798 ft. No discoveries of importance were made. In the Cochrane 938 ft. was driven on 550-ft. level, opening some high-grade ore. In the Silver Leaf some fair ore was exposed. The general situation made full capacity impossible at the Reward property. Porcupine Crown operations are reduced to development only.

Production: silver extracted from high-grade ore was 78,954 oz., and from mill ore 250,716 oz., a total of 329,670. To date the total is 19,960,676 oz. The cost was 55.6c. per oz., against 69.3c. in 1916, and 45.01c. in 1915.

KERR LAKE MINING CO.

Property: silver mine at Cobalt, Ontario.

Operating Official: H. A. Kee, manager.

Financial Statement: during the year ended August 31, 1917, ore sales realized \$1,887,118, and interest \$22,346, making a total revenue of \$1,909,464. All charges amounted to \$565,990, leaving \$1,343,474 available. Surplus at September 1, 1916, was \$1,033,570, and at August 31, 1917, \$1,711,044.

Dividends: amounted to \$666,000.

Development: new work covered 3105 ft., a decrease of 951 ft., due to labor shortage. This work was done in the more favorable portions of the mine. Some of it was disappointing. Reserves were not decreased to the full extent of the year's production, and are estimated to be 52,400 tons containing 898,900 oz., and 2,221,500 oz. in rich ore.

Production: 31,281 tons of ore treated by the Dominion Reduction Co. yielded 821,457 oz. silver, while 1,729,889 oz. was from shipping ore, a total of 2,551,346 oz. Cobalt in the high-grade ore amounted to 89,454 pounds.

LA ROSE MINES, LTD.

Property: silver mine and mill at Cobalt, Ontario.

Operating Official: G. C. Bateman, general manager.

Financial Statement: gross value of ore produced in 1917 was \$371,584. All charges were \$329,426, leaving a profit of \$42,157, plus \$29,090 from other sources, making a profit of \$71,247. Balance at end of 1916 was \$727,169, and at end of 1917, \$509,927.

Dividends: amounted to \$240,000, making \$7,475,410 to date.

Development: the work in La Rose was largely unproductive. Operations were stopped at the Lawson mine. No estimates of reserves are possible. Most of the dumps have been milled.

Production: the mill treated 44,451 tons of ore assaying 8.75 oz. per ton; of which 83.3% was extracted. Shipments totaled 1501 tons, of which 1187 tons was concentrate containing 273.33 oz. per ton. Silver production was 478,639 oz., making 24,205,968 oz. since 1908.

Costs: on a per ounce basis the total was 73.51 cents.

MCKINLEY-DARRAGH-SAVAGE MINES OF COBALT, LTD.

Property: silver mines and mill at Cobalt, Ontario.

Operating Official: T. R. Funicane, manager.

Financial Statement: net value of ore produced in 1917 was \$693,937. The total cost of production, including depreciation, was \$394,810. With sundries the year's profit amounted to \$259,795. The current surplus is \$242,514.

Development: in the McKinley mine new work covered 4686 ft. in the lower levels. A considerable tonnage of ore was blocked out, but no large bodies of rich ore. Reserves are estimated to contain 1,076,182 oz., excluding the silver in 200,000 tons of tailing, for which a plant has been erected.

Production: the mill treated 68,142 tons of ore averaging 13.434 oz. per ton. Extraction was 86.98%, yielding 796,298 oz. Silver shipped amounted to 1,020,545 oz., making 17,260,202 oz. since 1906.

Costs: on a per ton basis, \$6.934; on a per ounce basis, 57.09 cents. In 1916 the cost was 40.73c., in 1915, 28.71c.; in 1914, 31.32c.; and in 1913, 22.33c. per ounce.

NIPISSING MINING CO., LTD.

Property: silver mines and mills at Cobalt, Ontario.

Operating Officials: R. B. Watson, general manager; Hugh Park, manager; Jas. Johnston, mill manager; J. J. Denny, manager of research department; Chas. Butters, consulting metallurgical engineer.

Financial Statement: the gross value of silver produced in 1917 was \$3,756,890, of which \$2,686,472 was profit. Adding the balance from 1916—\$1,980,127—there was available \$4,666,599. After paying dividends the balance carried to 1918 was \$2,731,598.

Dividends: payments last year totaled \$1,935,000, making, with those in 1918, a total of \$17,730,000.

Development: new work amounted to 10,002 ft., about the same as in former years. A number of small veins were discovered, contributing an appreciable share of the year's output. Nearly all stoping exceeded expectations, and the previously known limits of a number of veins were extended. Vein 490 is one of the main sources of ore. On No. 5 level the shoot is 690 ft. long, and on No. 6, 660 ft. long. The stope above this level should be from 8 to 15 ft. wide over an average height of 110 ft. Reserves consist of 3468 tons assaying 1350 oz. per ton, and 134,240 tons of 25.3 oz., making 8,076,540 oz. available.

Production: the high-grade mill treated 1172 tons (excluding custom ore) of ore assaying 1960 oz. per ton, and the low-grade mill (40 stamps and cyanide plant) 73,015 tons of 31.13-oz. ore. Extraction by cyanide in the latter plant was 80.64%. The yield in 1917 was 4,212,248 oz. Since 1904 there has been shipped 48,827,808 oz. of silver.

Costs: on a per ton basis, \$14.26; on a per ounce basis, 25.117 cents. The latter is an increase of only 1c. over the previous year, a remarkable result considering conditions.

TEMISKAMING MINING CO., LTD.

Property: silver mine at Cobalt, Ontario.

Financial Statement: ore sales and bullion realized \$864,774, plus \$11,008 for interest, etc. Operations cost \$331,440, leaving a profit of \$544,342. Balance at credit at end of 1916 was \$671,000, making available \$1,215,342. After deducting dividends, etc., the current balance is \$814,557.

Dividends: five of \$75,000 each made a total of \$375,000.

Development: 4896 ft. of work was done last year. The main shaft was sunk to 1600 ft., just below the diabase sill, but nothing was found like that in the Beaver mine adjoining. Generally, the mine outlook is not encouraging, so an option was taken on the Hohenauer claim at Kirkland Lake.

Production: 958,670 oz. of silver was extracted at a cost of 31.56c. per ounce.

GERMAN officials in Belgium have tried their best, for four years, to kill 'La Libre Belgique', the irrepressible spokesman for Belgian independence. Recently it was announced by the German administration that the editors, publishers, and printers of this brave little paper had been arrested and sentenced, one of them to death. The next morning a copy of the paper was in its usual place in the letter-box of Baron von Falkenhausen, Governor-general of Belgium. 'La Libre Belgique' still appears—irregularly, it is true—but it is kept alive by the indomitable spirit and energy of a few courageous and persistent patriots. We salute our gallant contemporary!

A GROUP of 15 small producers of copper, representing an aggregate output of 75,000,000 pounds per annum, has formed a committee to ask for relief from the Government. These producers insist that they are an important factor in the total output; that those experiencing like difficulties constitute, in fact, a good-sized army, and that they are not able to produce copper at less than 30 cents per pound. They affirm that they have been operating at a loss in expectation of higher prices, rather than close their mines and suffer the further loss that always follows upon idleness of plant and disorganization. They are proposing a sliding scale of selling prices based on the cost of production as a feasible method of meeting the difficulty.

WE note that our New York correspondent comments upon the proposal to change the name of the Institute so as to specify metallurgy as one of the arts to which it is devoted. The idea has something to commend it, and our correspondent says so clearly, but we confess ourselves unsympathetic. If metallurgy is to be specified, then geology also should be mentioned. All the geologists that are members of the Institute are not mining engineers, but many engineers are geologists. No name to be given to the Institute can cover all the abilities and aptitudes of the profession. A mining engineer plays many parts, he must know something about many sciences, he necessarily is not a narrow specialist. The mining engineer is all sorts of an engineer. The objects of mining are to find, win, and beneficiate minerals and ores. To do that the engineer of mines must be a geologist, a miner, a metallurgist, a merchant, even a financier. No greater name exists in the annals of American en-

gineering than that of Alexander Holley, who shed lustre upon the Institute by serving as its President for a year. He is the supreme type of the mining engineer; he was a great miner, a great chemist, a leading hydraulic engineer of his day, and the most distinguished metallurgist this country has produced. It seems unwise to change the name of the Institute, now established by 47 years of useful service.

PROCEEDINGS now in progress at Chicago against the ring-leaders of the I. W. W. are almost overlooked in the midst of the stirring events of the day. It is well to call attention to the fact that the trial has conclusively proved that the organization was directing its efforts toward the closure of mines by fomenting strikes in a nation-wide conspiracy to hamper the United States in its plans for war. Enormous quantities of posters in three languages were distributed by the I. W. W. throughout the country, urging the laborers to strike and in other ways to impede the nation's preparation to resist Germany. The Teutonic influence appears in many forms, at one time in that of the rabid dynamiter posing as the representative of honest labor, and at another sentimentally whimpering for peace in the name of Christianity.

IN the editorial columns of the 'Financial Times', we find some highly interesting comment on the presidential address delivered recently by Mr. H. F. Marriott before the Institution of Mining and Metallurgy. Our contemporary in London declines to accept Mr. Marriott's "discovery" that there is no "general indication of depreciation of the gold values at depth" on the Rand. The Johannesburg correspondent of the 'Financial Times' points at the fact that the current market quotation of nine relatively young Far-Eastern Rand mines exceeds by several million pounds sterling that of the forty other productive mines on the Rand and asks "if the cause is not mainly deterioration of the Central Rand in depth, what is it?" We agree with this criticism, of course; we go so far as to say that Mr. Marriott's disingenuous treatment of the subject is not convincing, and was not convincing on other occasions when he has adverted to it, for it is unscientific; in short, it is too plainly a special plea made in the interest of the stock-market, the history of which, during the last ten years, proves

pitifully how the public has been misled by the financiers of the Rand and by their subservient henchmen. We shall return to the subject at an early date in order to discuss it with the thoroughness that its importance deserves.

KITCHENER is said to have remarked, "This is a war of machines, not a war of men." This sets forth one of the insistent aspects of the great struggle, although it is to be noted that today, as ever, the machine has to be directed efficiently if it is to be effective. The man behind the gun has not lost his essential importance. It was said recently by a British officer returning from the front that 80% of the work along the line of battle is engineering and 20% fighting. A little thought confirms the truthfulness of this generalization. Apart from the making of munitions and the equipping of armies, it is evident that the enormous masses of men now engaged in fighting call for a scientific organization of transport, the making of wagon-roads, the building of temporary railways, the erection of huts and hospitals, besides the digging of trenches, shelters, and saps. So necessary is this work of engineering that it has been found advisable to have men of engineering training not in special regiments but in every battalion, even in every company, so that at the pinch there may be somebody to show how to construct or destroy field-works, or otherwise direct the jobs that are bungled by those not possessing the special experience required in a hurry. In this war of nations it has been discovered that the civilian soldier holds an advantage over the man of purely military training in that he possesses initiatives and aptitudes acquired only in the pioneer life of the miner, the backwoods-man, or the cattle-ranger. The mining engineers in the British army have distinguished themselves greatly by bringing to bear the special knowledge gained in the waste places of the earth. Our own engineers have already begun to prove their practical usefulness amid circumstances that evoke the fullest use of that trained common-sense that we call 'gumption' because we dislike to apply to it the more pompous term 'science.' It is pleasant to think therefore that the miner and the profession associated with him will play a greatly honorable part in the tremendous struggle in which 27 nations are now engaged, not only in producing the metals urgently needed for the munitions and machines of war but in contributing a world-wide experience to the assembling and directing of the immense apparatus required to overcome the outlaws of civilization.

The Flotation Appeal

The metal-mining industry of the United States is to be congratulated on the outcome of the appeal made by the Butte & Superior Mining Company against the decision of the Montana court in the suit brought by the Minerals Separation company for infringement of patent and for damages. We give the full text of the opinion handed down by the United States Court of Appeals for the Ninth Circuit. The decision of the Montana court

is reversed, and the defendant company is released from a permanent injunction against the further use of the agitation-froth method of flotation. The opinion is written by Judge Ross, a Virginian jurist of fine classical and legal training, who also sat in the Hyde case; he is supported by Judge Hunt; while Judge Morrow concurs in the reversal of the decree of the lower court, but not "in the direction that the bill be dismissed." He does not agree with his two other colleagues in limiting the scope of the patent to the use of less than one-half of 1% of oil on the ore. For that is the keynote of the decision. Both litigants used the Supreme Court's decision in the Hyde case in their argument; they could not do otherwise; similarly the Appellate Court accepts the decision of the higher court; all it can do is to apply that decision to the case at issue. Judge Bourquin, of the Montana District Court, interpreted the Supreme Court's opinion in a manner that we thought illogical, and this view is confirmed by the reversal of Judge Bourquin's decision by the Appellate Court. The Supreme Court confirmed the validity of the Minerals Separation patent, but, recognizing how small had been the step taken by the Minerals Separation metallurgists in their improvement of the flotation process as disclosed by prior patents, they confined the Minerals Separation patent to results obtained by the use of oil within the critical proportions, as described in the claims of the patent and in the testimony on record in the Hyde case. Unfortunately, the Supreme Court did not go further, as it might have done, and state specifically what the 'critical' proportion was, that is, the Court did not state whether it was a definite fraction of 1% or exactly 1% of oil on the ore; hence the starting of the new litigation in which the Butte & Superior Mining Company became defendant as soon as it refused to accept the Minerals Separation interpretation of the Supreme Court's decision. The Supreme Court held the patentees to a fraction of 1%, not every fraction, says Judge Ross, for the Supreme Court accepted the evidence showing that granulation ceased, and flotation was complete, when the proportion of oil was reduced to 0.5%. The colloquy between Mr. Justice McReynolds and Mr. Kenyon is quoted by Judge Ross. It seemed to us highly significant at the time it appeared in the record of the case, and we noted its effect when it was read in the court-room during the proceedings on appeal. Judge Hunt quotes the specification in the patent setting forth that from 0.02 to 0.5% is a suitable proportion of oil for the process. From the evidence in the case, he concludes that the critical proportion is "very nearly one-tenth of 1% or two-tenths of 1% as may be required for a particular ore." Judge Morrow considers that if the Supreme Court had intended to confine the scope of the patent to a proportion of oil not exceeding 0.5%, it would have said so explicitly. Much of the testimony referred only to the use of oleic acid on Broken Hill ores, says Judge Morrow, therefore the scope of the patent was not confined by the Supreme Court to 0.5%, but was left open for the use of various proportions up to 1%, and inasmuch as the defendants "keep out of the

limits made for the plaintiff by the decision of the Supreme Court by using more than the critical proportion, they do not use plaintiff's process." This confirms the judgment of those that thought they could escape the claims of Minerals Separation by using more than 20 pounds of oil per ton of ore. The Court of Appeals holds that the patent (No. 835,120) does not cover the use of any particular kind of oil, and therefore that when the defendants are using kerosene or any other fuel-oil they are doing only what the patent authorizes, provided the proportion used is beyond the critical point, which is less than half of one per cent. However, the Court has made a curious blunder in assuming that the Butte & Superior Company "has never used in its process any oil in quantity as small as one-half of 1%," as stated by Judge Ross. The fact is that the appellant only began to use the non-infringing proportion of oil last year, as frankly admitted in the pleadings. The decree has just been modified in accord with this fact, thereby making the Butte & Superior liable for infringement from the beginning of its milling operations to January 7, 1917. At the present time the Butte & Superior, Utah Copper, and Chino companies are using over 10 pounds per ton, while the Ray uses less, but in connection with the air, not the mechanical agitation, method of flotation. The distinction drawn by Judge Morrow is interesting. We have directed attention, more than once, to the fact that the early experiments and several of the patents, notably No. 835,120, were based upon the use of oleic acid, a thick heavy oil quite unlike the frothing-agents now generally employed. The use of a thick oil like oleic acid was inherited from the Elmore process, for which heavy viscous oils were supposed to be best suited. Many statements concerning flotation with oleic acids are incorrect and misleading if applied to later work in this branch of metallurgy. That is why the series of experiments on which patent No. 835,120 is stated to have been founded is so unconvincing to those recently attracted to the study of the process. The fact is that, of course, Messrs. Sulman and Picard, of Minerals Separation, knew very little concerning the practical operation of the process when they applied for patent in 1904 and therefore they made a number of erroneous assumptions that have been crystallized in the course of litigation. Even today this latest decision of the courts and the record of evidence in the case lag considerably behind the technology of the subject. While experts and counsel argue about the efficacy of particular oils and assume the necessity for using some quantity of oil, some fraction of 1%, it is known to our readers that a 93% recovery of copper as chalcopyrite has been made with plain sea-water, without the aid of any kind of addition-agent. It seems queer to be disputing as to the proportion of oil that is 'critical' when no oil whatever is required in the flotation of some ores at least. The restriction of the patent to less than 10 pounds of oil is of the greatest importance, and it is one that seems to us wholly in harmony with the dictum of the Supreme Court. Therefore we expect it to be confirmed, if, as is likely, a writ of certiorari be granted for a final review of this case before the Supreme Court.

We have wondered often why the Hyde case was allowed to come before the Supreme Court after the Court of Appeals in San Francisco had given its decision; we conclude that the writ of certiorari was granted in deference to the British courts, quoted, quite mistakenly and improperly, in the Hyde case. The British decisions did not bear upon the matter at issue; they dealt with the validity of the older bulk-oil patents of Elmore, not the Minerals Separation patents. Again, it is not recognized generally how nearly the Appellate Court at Philadelphia reversed the Delaware decision in favor of the Miami Copper Company. Apparently the minority opinion was the majority decision until Judge McPherson changed his mind, as is suggested by the use of 'we' where 'I' would fit better in the context. We mention this fact to indicate how fortuitous the dicta of the courts have been and how important this latest, and we believe, penultimate, decision is destined to be to the mining industry.

The Real Sins of War

The world is now persuaded of the fallacy in the argument of the ante-bellum pacifists that there was a financial limitation to the ability of nations to carry on war. It is now seen that resources in men and in the products of the earth constitute the only limitation that controls a determined belligerent. We had grown so used to having our individual rights protected by the State, and had so long regarded a government of the people as being a servant of the people that we overlooked the fact that by its very nature a competent government must be sovereign. Indeed, we had forgotten the meaning of the word 'sovereign' and the fact that absolutism inheres even in the power established by the choice of free electors. Our readers must have been impressed by the good-natured indictment of the people of the United States in the cogent remarks by Capt. R. Hodder-Williams in our issue of May 4. He characterized us as an undisciplined nation. He gave a thrilling example of what discipline means, of the confidence that gives men the courage to rush forward in the face of death, and win, knowing that their comrades are disciplined and can be trusted to follow. This illustrates the moral quality that lies in discipline, the moral quality of a supreme duty. We were reminded that duty is the keynote of discipline. We had too much looked upon it as mechanical, for when it merely restrains the freedom of a people, as it does in Germany, it reduces man to a machine and destroys his initiative, which is the hope of all free and representative government. We had overlooked the necessary association of duties with the rights and privileges of citizens in a progressive democracy. Even the duty to study public affairs and to express our convictions at the polls had been shirked by an alarmingly great proportion of the voters. We are learning useful lessons from our experience in the hard realities of war. It is necessary to remind ourselves that the financiers are not the controlling influence in the councils of war, so that we may better interpret the true meaning

of the statistics of national finance. Some there are who still tell us that Germany is bankrupt, and consequently that she must soon weaken. It is important for us to remember that bankruptcy will not bring any government to its knees as long as it has men and material resources, and enjoys the confidence of the people. It is probably true that the morale of a country will suffer when normal business disappears, as it must when the credit-limit has been reached, yet Mexico went through just such a crisis, despite which a basis of domestic exchange has been evolved sufficient to encourage a moderate resumption of industry. The will to fight did not vanish even in the face of a fiat currency that had nothing behind it but guns and decrees. The same result might follow in a country that had been used to financial operations and industrial activities of great magnitude.

The strain of war upon the credit resources may be compared to the elongation of metal. It is not the tensile strength alone that must be considered, for that limit may soon be passed. The question is how far the metallic basis can be stretched before rupture ensues. When that happens the function of banks of issue has been superseded by the fiat of the supreme authority compelling the acceptance of inconvertible paper in all business transactions. At the outbreak of the War, for example, the ratio of gold and silver to the total note and deposit liabilities of the banks in France was 59.5%, and by January of this year it had diminished to 13.7. This is a severe decline, but not enough to destroy public confidence in the stability of the current medium of exchange. In Italy the ratio was 64.3%, and it has fallen to 11.5%. Great Britain makes a better showing with a ratio of 39.4% in June 1914, against 27.5% in January 1918.

A like comparison is not possible with the United States, as we did not enter the War until April 1917, and the pressure upon our resources may be said only to have begun. Our metallic reserve against note and deposit liabilities was still strong at the beginning of this year, being 61.7%. It is in Austria where the pinch has been felt most sharply, the decline having been precipitous from 63.4% to 1.1%. This indicates a financial instability that must be accompanied by great increase in prices, and it may help to explain the evident timidity of Emperor Charles and the peculiar tone of the utterances of Count Czernin on several memorable occasions. Austria undoubtedly is bound by financial and other bonds to Germany so that she cannot pretend to be in any sense a free agent, but warrant is found in these conditions for President Wilson's belief that she would be glad to find some avenue of escape from her dilemma. Meanwhile her debt has risen from \$3,985,000,000 in 1914 to \$15,000,000,000 at the present time. It is clear that she has not been permitted to profit from the loot and tribute obtained by Germany. In fact, although an ally in name, she has been fettered by financial chains clamped upon her by her Prussian masters. The debt of Germany has augmented from a pre-War figure of \$1,165,000,000 to \$24,243,000,000, yet her banking con-

ditions have not suffered proportionately. The ratio of gold and silver to her total note and deposit liabilities has decreased from 36.7 to 13.3%, while the gross metallic reserves have actually grown from \$363,700,000 to \$615,292,000. In Austria the reserves have dropped from \$311,963,000 to \$64,657,000. Apparently the precious metal has flowed in a steady stream from Vienna to Berlin. It is interesting to note that the countries not actually participating in the War generally have strengthened their financial position. Spain has more than doubled her metallic reserve, so that today she boasts a ratio to outstanding obligations of 71.5%. Holland has made proportionate gains, though the actual volume of increase in the gold reserve has been only about half as great. Sweden, Denmark, and Switzerland have all suffered, apparently because of propinquity to Germany, entailing the necessity for conducting an immediately unprofitable commerce with their threatening neighbor. Japan has been nominally in the War, but has not been using up her resources as have the powers with whom she is allied. She has benefited by her relations with all of them except Russia. The metallic reserve underlying the notes and deposit-liabilities of her banking system have risen from \$112,296,000 in 1914 to \$326,982,000 at the present time, constituting ratios respectively of 41 to 46.6%. As a creditor nation she has greatly strengthened her resources, despite the uncertain value of the \$85,000,000 loaned to Russia. She has advanced \$140,000,000 to Great Britain, and \$38,000,000 to France. Furthermore, the total volume of deposits in Japanese savings banks has been larger than her internal loans negotiated during the War. The financial strength of Japan has become the chief factor in the adjustment of affairs in the Far East. The extension of the privileges acknowledged first in the Lansing-Ishii agreement she has further confirmed through making the other powers her debtors, in which she has not failed to include China. On the opposite side from this example of liberty to augment her prestige and financial influence, accorded by the Allies to one of their number, is the case of Austria looted to the point of helplessness by the imperial nation to whose hopes of victory she is absolutely essential. The economic weakness of Austria, however, must not be taken to imply that she can be detached from the fortunes of Germany. She has become her vassal, and will so remain until Germany's man-power has been exhausted. Germany's financial status will not wreck the Prussian, for indebtedness does not argue lack of resources. When, however, the real sinews of war in men and supplies become reduced too low for further resistance then the economic distress in Austria will hasten her downfall. Meanwhile we must regard any statement of banking difficulties in this or in any of the Allied countries as having no significance regarding our ability to wage a conquering war. Our strength lies in our inexhaustible resources in supplies and in men, all of which, and all of whom, our quickened perceptions of duty now show us belong to the sovereign State we have erected as a united people in willing discipline for the common good.

DISCUSSION

The United Verde and Labor

The Editor:

Sir—My attention has been called to an article that appeared in your issue of April 6, wherein you comment upon matters as you found them in Arizona during your visit there last year. I believe that, in regard to many of these matters, you have been misinformed, and I hasten to correct any wrong impression that you may have had.

In the first place, in regard to the strike in the Jerome district, which was in the latter part of May 1917, you make the statement that it was your belief that this strike could have been avoided, if the United Verde Copper Co. had used firmness and fairness in its dealings with the men. I have active charge of the United Verde, and the facts in regard to the strike are as follows:

I was in New York early in May, and at that time knew there was something in the air in regard to a demand for increase of wages, etc. I took up the matter with my assistant, Mr. Tally, at Jerome, and wired him finally to put into effect the Miami scale of wages, believing that it was better to have a uniform scale in Arizona, although our scale at that time was approximately the same as the Miami. About a week after this I was waited on by a committee consisting of Moyer, president of the Western Federation of Miners, Lord, Cannon, and Burns. They were with me about two hours and their plea was for the closed shop. This I absolutely refused, and the matter stood in this way until the latter part of May, when the strike was declared at Jerome. Thanks to about 300 Mexicans, who refused to go out, and to the efficiency of our underground bin system, we were able to continue operating during the two weeks that the strike lasted, although, of course, on a reduced scale.

The Governor of the State, the representative of the War Department, and the representative of the Department of Justice were in Jerome during this strike. The strike ended by the men coming back to work on exactly the terms I had offered before they struck and when their demands were first made, and that was by my allowing a grievance committee to be appointed, but by my refusing the closed shop. I cannot see that there was any lack of firmness here.

Your comments in regard to the physical conditions of Jerome itself are true. It is unfortunately located on a steep hillside, which makes building very difficult, so that it is, I admit, an unsightly point. However, so far as we are concerned, we have endeavored to make it as livable as possible for our men. We had, at the time of

the strike, about 80 houses which were rented to our men, and I have since built 30 more at Jerome. These we rent at a price so low that our real estate account for the last 15 years has always been a losing one. It is true that rents, generally, in Jerome are very high, and the reason for this is as follows:

When the United Verde Extension mine developed into such a fine producer, there were many 'wild-cats' started at Jerome, and the town, within a short time, doubled its population. People who owned houses, regardless of whether they were mere shacks or not, took advantage of this situation to raise their rents, and I have been informed that a number of strong union men were among those who owned shacks and took advantage of this situation. We, ourselves, continue to rent our houses to the men at the same prices as before, and that is from a third to a half of what others charge.

So far as actual living expenses in Jerome are concerned, the recently appointed Federal Administrator for Arizona, Mr. Joseph Myers, made a thorough investigation and report, and his findings were, that living costs at Jerome were as cheap as in any camp in the West, and cheaper than in most of them.

You refer in your letter to the rather uncomfortable railway terminal, and this is admittedly so, the main reason being that we have been obliged to put our station away back on the hillside in order to prepare for the large steam-shovel operations which we are now about to undertake; but, as a remedy for this, we are constructing now a road from the mouth of the Hopewell tunnel, to which point our Verde tunnel and smelter railroad connecting at Clarkdale with the Santa Fe runs, to a point at Jerome, which will greatly facilitate passenger and freight traffic.

You intimate in your statement that a shorter road to Prescott could be built, but you must be aware that this would be a physical impossibility. We have always been anxious to have a closer business relation between Jerome and Prescott, and for this reason I recently offered to finance, with the United Verde Extension, a fine automobile-road connecting the two points.

I should have been pleased, while you were at Jerome, to have shown you our town of Clarkdale, which is admittedly the finest smelter town today in the world. The buildings are beautifully built, the business houses are attractive, the school is most modern in every way, and everything in the way of hygienic precautions has been taken to insure as near a perfect condition of health for the inhabitants as is possible. Being within about half a mile of the smelter, where the stack is 400 ft. high, the

smoke has at no time within the last two and one-half years that the smelter has been in operation, caused the slightest trouble.

Our relations with our men now are most amicable. I believe that our men, as a whole, are peaceable and yet, in this great crisis, most patriotic. I will state that during the recent Third Liberty Loan drive, without extra solicitation on our part, every man in the employ of the United Verde Copper Co. purchased a liberty bond, and the average was about \$80 per man. Considering the fact that we are about 70% foreign in our make-up, I consider this a wonderful record.

Your article was taken advantage of by the 'Arizona Labor Journal' to create a false impression concerning conditions at Jerome, and I think that, in justice to Senator Clark, who has operated in Jerome for thirty years, and generally in the West for about fifty years, during all of which time there has been but one strike on any of his properties, and to myself and my associates, I should set forth exactly what the facts are.

CHARLES W. CLARK.

San Mateo, California, May 17.

[We are most willing to give Mr. Clark an opportunity to make this courteous criticism. The writer of the article—the editor of this paper—did visit Clarkdale and is glad to testify to the excellent arrangement of that smelter settlement. It is all that Mr. Clark says of it. Of course, the writer was not aware that it was "a physical impossibility" to build a road to Prescott, otherwise he would not have made the suggestion, which came to him from one supposed to be thoroughly well informed. In regard to the events preceding the strike and the general treatment of the men employed by the United Verde company, we accept Mr. Clark's correction, with pleasure.—EDITOR.]

Extraction and Recovery

The Editor:

Sir—In metallurgical operations there is considerable confusion in the correct use of these terms. If a gold or silver-mining company report that its 'extraction' last year was 95%, it means that the bullion actually 'extracted' was 95% of the original metal-content of the ore.

If a copper company report 71%, it means that by concentration there was 'recovered' 71% of the original metal. Probably when the concentrate is smelted, the total actual 'extraction' would be under 70%.

The 1917 report of the Kennecott Copper Corporation states that the total average milling 'recovery,' including ammonia leaching, was 89.4%. This is correctly stated.

In describing the New Cornelia leaching plant, L. D. Ricketts said that the 'recovery' was nearing 80% of the copper-content of the ore. In wet-chemical methods of treatment, such as the one described, the 'extraction' of the metal from the ore by means of a solvent is not to be confused with 'recovery'; and the calculation of percentage recovery is the basic factor on which considera-

tions of ultimate success or failure can alone be gauged.

Concentration at Burro Mountain is reported to have 'saved' 72.258% of the copper. This means 'recovered' not 'extracted.'

In describing the concentration of carnotite ore, Bulletin No. 103 of the U. S. Bureau of Mines says: "As much as 63.7% of the carnotite contained in the milling ore was 'extracted,' and 60% of all the carnotite in this ore was actually 'recovered' in the concentrates (four grades), on the basis of the uranium content determined by chemical analysis. In this statement 'extraction' is considered as the difference between uranium oxide content in the feed and in the tailing, whereas 'recovery' is considered as the actual uranium content in the concentrate expressed as a percentage of the uranium content in the feed.

M. W. VON BERNEWITZ.

San Francisco, May 17.

Treatment of Tungsten Ores

The Editor:

Sir—I believe I can contribute something to those interested in mining scheelite ore. When I came into the Atolia and Randsburg districts about three years ago I found all the mills crushing with stamps or ball-mills. Now scheelite and other tungsten ores are in the shape of crystals, and these when pulverized will 'flour'. To granulate is evidently the proper thing. Accordingly, for a crusher I got the Moyle roll jaw-crusher; then I put in a set of rolls, with a shaking-screen under both the crusher and the rolls. It proved best not to crush finer than 20-mesh. After looking over the field I got an Overstrom 'Universal' concentrator-table, and the Hamill ore-feeder. When I put that before the concentrator, I increased the output two tons in eight hours. I am now getting a recovery of better than 85%. The completed mill did not cost more than \$4000, and it treats an average of 30 tons in 24 hours.

The conditions of the tungsten market also deserve a word. At present it seems that there are no buyers in the field. What is the cause? Is it that the Government is going to set a price and take it out of the hands of the brokers, or is there an over-supply? I read in the papers that the Government was going to try loaning money to the small mine-owner and prospector, to encourage greater activity in mining and a larger output. That is not the main difficulty. What we want is to get a steady and reliable market for our tungsten, say, at a price of about \$30 per unit, and the prospectors, leasers, and mine-owners will get busy and will not need financial assistance from the Government. Just fix a fair price and we will do the rest. With the cost of powder and wages and living as they are we must have a price for the output that will enable us to run, or we will have to shut-down. I can count 25 properties now that are idle on account of the slump in the price; we are now offered only \$20 per unit for ore assaying 65%, or better.

J. H. RATCLIFFE.

Randsburg, May 15.

Smelting Methods at El Paso—II

By COURTENAY DE KALB

COPPER SMELTING. The copper department of the plant contains four reverberatories and four blast-furnaces. The latter are 144 by 44 in. at the tuyeres, and 14 ft. high from the sole-plate to the top of the water-jackets at the feed-floor. The hearth is of cast-iron with a 6-in. fire-brick lining. The tuyeres are $3\frac{1}{2}$ in. diameter, and the blast-pressure is $2\frac{1}{2}$ to 3 in. of mercury. The rate of smelting per furnace averages 275 tons of charge per day, with 10% coke. The copper content varies from

discharged through a special sheet-copper spout, shaped and riveted at the plant, 2 ft. 6 in. long by 1 ft. 6 in. deep, water-jacketed, as shown in the accompanying illustrations, and fitted with a cast-bronze nose. The composition of the bronze is 98.5% copper and 1.5% tin. The spout lasts for years, but the wear of the running matte and slag cuts out a nose in six or eight months. From this spout the slag and matte empty into a round forehearth in front of each furnace, this being

OIL-BURNERS, SLAG LAUNDER, AND GATE LEVERS OF NO. 4 REVERBERATORY FURNACE

6 to 12%. The slag-type aimed at is approximately as follows:

Typical Analyses of Copper-Slags

	%	%	%
FeO + MnO	38.6	38.7	42.0
SiO ₂	39.1	36.0	36.1
CaO	11.2	13.3	10.5
MgO	0.5	0.5	0.5
Al ₂ O ₃	7.4	7.0	6.8
Cu	0.48	0.42	0.50

The relatively high copper in the slag as shown in the foregoing analyses is the result of so running the furnaces as to produce a high-copper matte, which in these cases contains about 45% copper.

The products of fusion from each pair of furnaces are

14 ft. diam. by $4\frac{1}{2}$ ft. deep, made of $\frac{7}{16}$ in. steel sheet. These hearths are lined on the sides with 9-in. magnesite or chrome bricks backed with 4 in. of fire-brick, leaving a 2-in. space between the brick wall and the steel shell, which space is filled with brasque, that is, a mixture of fire-clay with about 3% of coarsely granular coke. This forms an excellent non-conductor. To a slight extent the coke is consumed, thus helping to protect the brick wall from expansion, since the coke, while fairly resistant, will crush under the pressure. The bottom, also of steel, carries a layer of sand followed by a course of 9-in. fire-brick placed on end. At the matte-tap, and under the overflow spout, the magnesite is materially thicker. The

matte, which has an average content of 45% copper and 21% sulphur, is tapped into ladles and taken to the converters.

The reverberatory plant presents features of larger interest. There are three in operation and a fourth just entering service. These are working mainly on Chino concentrates, both from flotation and from table concentration, the ratio being about one to five. Typical analyses of these are given below:

Chino Concentrates

Flotation concentrate				Table concentrate			
%				%			
1	2	3	4	1	2	3	4
SiO ₂ . . .	24.7	22.8	26.5	25.9	9.4	14.2	21.5
Insol. . .	35.6	31.9	37.5	38.0	13.3	17.7	28.4
FeO . . .	20.7	13.2	20.4	19.5	47.8	36.0	23.7
Cu . . .	19.3	21.9	19.7	19.8	10.8	26.7	28.1
S . . .	13.7	8.7	14.0	12.3	36.4	16.2	13.2

The oil-flotation concentrate presents some difficulties in roasting. The oil and moisture cause agglomeration, decrepitation is prevented, and unroasted kernels come to the reverberatory-feed, some of them having had a diameter as great as 4 inches. The outer one-eighth to three-sixteenths of an inch will be roasted; inside of this shell will be another of darker color, and about three-eighths of an inch thick; while the centre will be raw. It is highly probable that the agglomeration may in part be produced by an excess of alumina. The table concentrates also have caused trouble from the large amount of magnetite that they sometimes carry, but some of this mineral is now being removed at Chino with magnetic separators. The water in the concentrate when it is delivered to the drying-hearth of the Wedge roasters ranges from 4 to 18%, and regularly averages 10%. Even the first hearth serves also as a dryer, and samples from the ports of that hearth contain appreciable amounts of moisture.

Roasting is done in a battery of eight Wedge furnaces, with five hearths each 21 ft. 6 in. diam. Four new 7-hearth furnaces are being added. The speed of the roaster-arms is regulated by resistance-coils under control of the furnace operator, and the time of revolution varies from one in 21 to one in 59 seconds. With Chino concentrate the capacity of each furnace is from 155 to 175 tons per day. The sulphur in the feed to the roasters is usually about 14%, though at times it runs above 20%, and the elimination is only from 5 to 7 units. Therefore the calcine issues quite hot, the lower hearth showing a temperature of about 1000° to 1200° F. Auxiliary heat is applied with three to four oil-burners on the first and third hearths. In order to make the desired 45% copper matte the following ratios are maintained in the feed:

Ratio of copper to sulphur	1:1
Ratio of copper to iron	2.14:1
Ratio of copper to base	1.2:1

The Chino concentrate is nearly barren of precious metals, the average content being about 0.02 oz. gold and about the same quantity of silver. With such small quantities the percentage of losses, of course, is high. From

other mixtures more precious metal enters the matte, which usually contains about 0.04 oz. gold and 2 to 6 oz. silver. For comparison it may be well to mention at this point that the precious metal in the anode plates shipped to the refinery averages, at the same period of sampling, 0.20 oz. gold and 12 oz. silver. However, these anodes represent a mixture of blast-furnace mattes higher in metals. Reverberatory-slag samples range in composition between the percentages given in the annexed table:

Reverberatory-Slag Analyses

	1	2	3
	%	%	%
Silica	36.9	38.7	41.3
Iron (FeO)	42.0	40.5	39.0
Manganese (MnO)	0.5	0.7	0.5
Lime (CaO)	6.5	6.5	5.8
Zinc oxide (ZnO)	0.8	1.0	0.9
Alumina (Al ₂ O ₃)	8.4	6.6	8.3
Copper (when producing 30% matte)	0.32	0.34	0.38

The oxygen ratio, therefore, fluctuates between the limits of 1.5 and 1.25, or between a sesqui and a uni-silicate. This is not highly basic for a reverberatory slag, though its relative viscosity is quite evident from the rather steady content of copper at 0.35% or a trifle higher. The blast-furnace copper-slugs average 37% SiO₂, 38 FeO, and 11 CaO, which is a bi-silicate, with an average copper content of 0.46%. In the reverberatories, with the mixtures now smelted, fluctuation of the silica seems to exert no effect on the copper or silver, but with too low a silica content an exceedingly viscous zone rich in copper and magnetic iron forms in the slag just above the matte-line. Increasing the silica dissipates it by taking up FeO from the Fe₂O₃, and then the further reduction of the Fe₂O₃ takes place. A similar effect is observed upon the increase of temperature, whereupon the magnetic iron disappears. This, however, cannot be maintained for any lengthy campaign, as the brickwork cannot long withstand such high temperature.

Of the reverberatories now under heat two measure 104 by 19 ft., and another 118 by 25 ft., while the new one is 130 by 30 ft. These are equipped with a battery of 11 Erie boilers in the flues to generate steam from the waste heat. The new furnace is designed in accordance with the plan for feeding used on the 118-ft. furnace, which is now becoming general in reverberatory practice. This is to omit fettling, in the old sense, and merely to feed the calcine and ore along the two side-walls of the furnace. Many years ago at Cananea, under the administration of L. D. Ricketts, this logical system was used in the form of feed-holes in the roof of the furnace just inside the walls, and through these holes silicious ores were fed as fast as the bank that dammed the slag from the wall was consumed. It is curious to realize how slow we are, after all, to think the next necessary thought. Today the maximum part of the charge is fed through ports on the side, just as silicious ore was fed as a fettling at Cananea 10 years ago. There is this difference, however, which marks a further advance in the art; instead of being held by the force of ancient

custom to maintain a low bank of ore, as was done at Cananea, following the conventional idea of fettling, the charge is fed freely, and is piled high along the walls. The furnace is accordingly widened to admit of these banks, which gives to the laboratory the shape shown in the accompanying cross-section. Moreover, this protects the walls, adding to the life of the furnace, and it prevents radiation of heat, thus introducing fuel economies, which cheapen the cost of the copper produced. Not only does it protect the walls against cutting out from fusion, but it overcomes the destructive effects of expansion and contraction when feeding, skimming, and the like. Some feeding is still done through charge-ports in the centre of the roof, since this is necessary for regulating the smelting conditions, but the charge is introduced chiefly through the side-ports. Charging is done from the rear of the furnace through two-thirds of the distance toward the front, the remainder being fettled with silicious ores, also introduced through side-ports. The molten bath always displays a tendency to eat into the wall, now at one place and now at another. As the conditions of feed and the sweep of the flame undergo changes the bath responds, and refuses to conform to the geometric design of the furnace. The method of fettle-feeding, as it may be called, gives flexible walls to the molten bath, so that it may accommodate itself to the changing conditions without doing damage to the furnace. The illustration shows in outline the vagaries of the bath within its sloping walls of reacting ore. The swing of the molten lake always makes a bay toward the matte-tap, which never becomes obliterated, and it also widens toward the skimming-door. Once every hour and a half to two hours the slag is skimmed, while the matte is tapped as often as necessary, depending on the speed of smelting and the copper content of the charge. The normal rate of smelting in the 118-ft. furnace has been 450 tons of charge per diem. Recent improvement in the detail of operating has increased this to about 675 tons of solid charge, with an oil-ratio of 0.72 bbl. consumed per ton smelted after giving credit for heat-recovery in steam produced. As the material going to the furnaces has not been as favorable for rapid work as usual, it would seem likely that a still larger average capacity will be attained. This striking gain has been achieved by localizing the smelting zone, that is, by so regulating the oil and air as to prevent the flame extending beyond the first 50 or 60 ft. of the furnace, and at the same time by limiting the charging to the first 60 or 70 ft., leaving the remainder of the hearth to constitute a pool where the matte settles from the molten charge. The temperature at the skimming end of the furnace, about 12 ft. from the up-take flue, under these new operating conditions, varies between 1950° and 2300° F., which is approximately the same as that registered before when the flame was allowed to sweep practically through the full length of the furnace.

CONVERTING. The Great Falls type of converter has been superseded at El Paso by the Pierce Smith barrel-type. All trace of the jug-shape is gone; even the belled-

form has disappeared. On the exterior it appears like a large horizontal cylinder, 30 ft. long and 13 ft. diam., with a flaring mouth in the position of a bung. Actually there is a 'false shell' opposite the mouth, cutting off a segment on a larger radius for the true bottom of the converter, thus making it flatter below, and reducing the depth of the molten charge within. The outer shell, under this segmental bottom, has large holes cut through it, permitting escape of heated air but also conserving some of the heat. The result of this arrangement is to overcome the tendency to form bottom-accretions, the brick lining seldom accumulating a layer thicker than three to five inches. The basic-brick lining is a magnesite brick 32½ in. thick on the ends, 18 in. on the rear semi-circle, and 13 in. on the front, leaving the effective inner dimensions 24 ft. 7 in. long by 10 ft. 5 in. diameter. There are 41 tuyeres in a row on the rear side, with the centres 14 in. below the estimated level of the bath when blowing. The depth of the bath varies from 40 to 60 in. The blast-pressure is 13½ to 14½ lb., and the volume of free air delivered per ton of copper is from 170,000 to 200,000 cu. ft., depending on the grade of matte being blown. The main supply of matte comes from the reverberatories and averages about 30% copper, while the blast-furnace matte carries from 40 to 50%. A full converter-charge of 30% matte is 225 tons, which will yield about 60 tons of blister. The initial charge of 30% matte is 64 tons. This initial charge consists of four ladles of 16 tons each. Then one or two more is poured in every 50 minutes, the converter being skimmed before each fresh addition of matte. An interval between successive charges of one-half hour to one hour is necessary for cleaning tuyeres, stack, and the like. This, however, is good practice, as it allows the hardening of the brick, which becomes slightly plastic under prolonged heat, due to the finish-blow, thus greatly prolonging the life of the lining. A record of one of these big converters, before repair of the lining was needed, is a remarkable example of the efficiency that is being attained in this branch of copper smelting. The total days' run, not counting lost time, was 318, and the blister-copper produced was 22,530 tons. At the end of this campaign the following magnesite bricks were all that the converter required to equip it for renewed service:

Kind	Size, in.	Number
Keys	13	42
"	18	470
"	9	200
Wedges	9	63
Splits	9	70
Rectangular brick	4 by 4 by 13	430
"	2 by 4 by 13	130
Magnesite cement		5200 lb.

The above result is particularly noteworthy, considering the irregularity in the quality of the matte incident upon custom-smelting. With a more uniform matte the life and corresponding output of the converter would be greatly increased. There are two stands of these large converters and one of the old Great Falls type, 12 ft. diam. The silicious ore is fed into the large

FRONT OR SKIMMING END OF NO. 4 REVERBERATORY

FRONT END OF CHARGE-FLOOR AND UP-TAKE FLUE, NO. 4 REVERBERATORY

cylindrical converters by a Garr gun, which is a cylinder attached to the upper segment of the shell through which silicious ore is blown into the converter by an air-blast. The ore, crushed to $1\frac{1}{2}$ in. and smaller, is delivered into the path of this blast from a small feed-hopper. It has proved a great economy, and causes no disturbance in the condition of the bath as does intermittent charging. The silica is added as it is needed by the oxidizing iron. The same attachment is being adapted to the Great Falls converter now in use at this plant. It is to be observed that copper metallurgists are not disposed to regard the type of converter as being more important than the right proportion of size to the amount of matte to be converted. A small converter in a plant may be extremely useful at times when the reverberatories are low in matte, by giving greater flexibility to the operation. The converter-fume is drawn into a balloon-flue of 250 sq. ft. sectional area, and 400 ft. long, connecting with a stack 300 ft. high and 16 ft. diameter at the top. The temperature of the gases entering the stack is about 300° F. The blast is supplied to the converters by two Nordberg blowing engines and one turbo-blower. The blowing engines are rated respectively at 18,000 and 12,000 cu. ft. of free air per minute delivered at 14-lb. pressure per square inch. The turbo-blower, rated at 30,000 cu. ft. of free air per minute, is a turbine at each end, the driving-turbine taking exhaust from other engines supplemented by live steam at 140-lb. pressure, the air being delivered against 14 lb. per square inch at the altitude of 3800 ft. above tide. It runs at 3350 to 3650 r.p.m., and registers 2000 brake-horse-power. The steam-turbine is made by the Ridgway, Rateau-Smoot Co. of Ridgway, Pa., and the blower-end by the Rateau-Battu-Smoot Co. of New York. The converters are operated by the usual rack and pinion movement driven by a 75-hp. Shaw & Co.'s motor, and the shifting of ladles, shells, and other burdens is accomplished with a 60-ton 90-ft. span Shaw overhead crane, with auxiliaries, one of 30-ton and the other of 15-ton capacity.

REFINING. The molten blister copper is poured into ladles, and these are emptied into one of a pair of 145-ton tilting furnaces. These furnaces resemble in some respects an open-hearth steel-converter. The hearth-frame is of steel resting on wheels adapted to the curved bearing-bars, and is tilted for skimming and casting in the same manner as the converters. The hearth is lined with magnesite brick, and the top is a flat magnesite-brick arch, with low brick walls, all securely ironed. The inner laboratory dimensions are 8 by 30 ft. The receiving-spout or charging-door is placed centrally at one side just above the hearth, while the pouring-spout for the copper is opposite, and at a slightly lower level. The furnaces are oil-fired, and consume a total of 24 to 30 bbl. each per day. At one end is a work-door set in the brick wall, through which the copper is further refined by poling in the old-fashioned way for reducing the cuprous oxide and for expelling the dissolved SO_2 . For this purpose green quaking asp poles, brought from Cloudercroft, New Mexico, are employed. The poles are

30 ft. long, 8 in. diam. at the butt, and tapering to 4 in. at the small end. For refining the output of 4500 tons of copper per month about 388 poles are required. The copper is poured into a cement-lined hydraulically operated tipping-spoon and thence into a revolving casting-machine, making anode plates 2 in. thick and weighing 725 lb. each. The molds are of similar refined copper, having an iron splash-plate cast into them at the point where the stream of copper will fall. These molds are cast at the El Paso smelter. The anodes are shipped to Baltimore for electrolytic refining. The complete analysis of the anodes shipped is approximately as follows:

Analysis	
Copper	99.6 to 99.75
Lead	0.02 to 0.025
Nickel	0.057 to 0.062
Arsenic	0.0064 to 0.01
Antimony	0.0056 to 0.011
Sulphur	tr. to 0.01

DUST-LOSSES. From the converter plant the total gas passing out of the stack is about 230,000 cu. ft. per minute. The dust-losses from the lead furnaces, as already explained, have been reduced by the use of the draft-hoods. The gas from the lead furnaces is combined with that from the copper blast-furnaces at the stack. The total volume of gas, reduced to 70° F., is 150,000 cu. ft. per minute. This is carried by an octagonal brick stack 225 ft. high and 15 ft. diameter at the top, discharging into the air at a temperature of 160° F. At a height of 60 ft. above the base, the gases have a temperature of 200° F. At this point the gases are sampled by drawing off a measured volume by a suction-blower giving the same speed to the sample as the velocity of the gas rising in the chimney. A tube $3\frac{1}{4}$ in. internal diameter by 12 in. long is fixed centrally in the stack in a vertical position, with the open end turned downward. This is connected by long-sweep reducing-elbows to a 2-in. pipe projecting through the wall, and connected to an experimental filtering-bag. The dust gives a neutral reaction, but in wet weather corrosive compounds are formed that rot the cotton filter-bag.

The general manager of the El Paso smelter is Kuno Doerr. The general superintendent is J. Heggie. The lead plant is in charge of the assistant superintendent, C. W. Badgley, while the copper plant is operated under the direction of A. F. McCormick, assistant superintendent. The plant is operated on a highly economic basis, despite the disadvantages of an inconveniently crowded site and methods of handling that seem crude in these days of automatic devices, but that are the necessary consequence of local labor conditions and of a custom business that gives no opportunity for delays in remodeling. It is a plant where careful management and ingenuity are of prime importance.

COPPER produced in the United States in 1916 from ores in which this metal constitutes the principal value totaled 1,969,403,226 lb. This was extracted from 57,863,365 tons of ore, which averaged 1.70%. The gold and silver value of this ore was 42 cents per ton.

Minerals Separation v. Butte & Superior

OPINION U. S. CIRCUIT COURT OF APPEALS

This is an appeal from the decree of the United States District Court for the District of Montana, sustaining Letters Patent No. 835,120, issued to Sulman, Picard, and Ballot on November 6, 1906, for a process of ore concentration, and adjudging the appellant herein to have infringed the same.

The appellees, two British corporations and one domestic corporation, are the legal owners of the title to the patent in suit, and of the rights to profits and damages for infringement thereof. The appellant is a domestic corporation, doing business at Butte, Montana, where the acts of infringement complained of were committed.

The suit was commenced on October 10, 1913, and a preliminary injunction sought. At the hearing on the motion for a preliminary injunction the pleadings and proceedings in the suit of Minerals Separation, Limited, et al, v. James M. Hyde, in the United States District Court for the District of Montana, were offered and received in evidence, and are a part of the record herein. That suit was upon the same patent and the issues were substantially the same as in the present case.

The answer of the defendant set up the defence of anticipation, and denied infringement. While the cause was at issue, but before trial on the merits, the Supreme Court of the United States rendered its decision in the Hyde case (242 U. S. 261), holding Claims 1, 2, 3, 5, 6, 7, and 12 of the patent to be valid, and Claims 9, 10, and 11 to be invalid.

The plaintiffs filed a supplemental and amended bill on May 1, 1917, during the trial of the case on the merits, pleading a disclaimer filed by them on March 28, 1917, and charging continued infringement of Claims 9, 10, and 11 of the patent, as limited by said disclaimer, and of the remaining claims.

To the plaintiffs' supplemental and amended bill of complaint defendant filed its answer on May 4, 1917, denying infringement and the validity of the patent by reason of lack of novelty and invention; alleged, further, that the patent had become wholly void and invalid by reason of the unreasonable neglect and delay of the plaintiffs to file a proper or any disclaimer in writing to Claims 9, 10, and 11, held to be invalid by the Supreme Court in the Hyde case; alleged, also, an estoppel against the claim of infringement by the use by the defendant of an amount of oil exceeding five-tenths of one per cent on the weight of the ore, basing this defence upon a statement made by one of plaintiffs' counsel in the Supreme Court of the United States in the Hyde case, that the invention described in the patent was not reached or practised until the amount of oil fell to or below five-tenths of one per cent on the weight of ore treated by the process.

Upon the issues thus presented voluminous testimony was taken upon all the questions involved, which, as stated, were substantially the issues in the Hyde case, re-stated and re-considered by the lower court in the present case.

The Court thereupon entered a decree in favor of the plaintiffs, in accordance with the conclusions of the opinion, holding that the plaintiffs were the owners of the patent in suit; that the processes employed by the defendant both before and after the filing of the bill of complaint, to and including January 7, 1917, embodied the invention of the patent and infringed Claims 1, 2, 3, 5, 6, 7, and 12 thereof, and Claims 9, 10, and 11, as limited by said disclaimer; and that the processes employed by the defendant from the 7th day of January, 1917, down to and through the time of the trial, embodied the invention of the patent and infringed Claims 1, 2, 3, and 12 thereof, and Claims 9, 10, and 11, as limited by the said disclaimer. The decree granted a permanent injunction against the further use of such process by defendant, and directed that an accounting be had for the assessment of damages accruing from such use. From that decree the defendant has appealed to this court.

Before ROSS, MORROW, and HUNT, Circuit Judges.

ROSS, Circuit Judge:

Notwithstanding the strenuous contentions on both sides of this litigation, the very elaborate preparations, and able arguments of many distinguished counsel, we can but regard the case as a very plain one.

To start with, the law is too well established to require discussion or the citation of authorities, that the patentee's rights under a patent are governed and limited by its valid claims—its specifications being referred to only as illustrative of the true meaning of the claims. It is equally well settled law that the mere result of an invention is not patentable; nor is froth, or seum, or pine-oil, or any other kind of oil, or oleic acid, patentable as such.

In their specifications the patentees of the patent in suit declare that their invention "relates to improvements in the concentration of ores, the object being to separate metalliferous matter, graphite, and the like, from gangue by means of oils, fatty acids, or other substances which have a preferential affinity for metalliferous matter over gangue;" but of the claims of their patent adjudged by the Court below to have been infringed by the appellant, not one specifies any particular kind of oil, although the fifth and sixth specify as one of their constituents "a small proportion of oleic acid (which is an acid existing in most fats in combination with glycerol), amounting to 0.02-0.5 per cent on the ore." And we do not understand it to be contended that the appellant uses any oleic acid in its process.

It is not denied that at the time of the invention in question the affinity of oil for the metalliferous portion of powdered ore, when mixed with water, was well known, as well as the further fact that the agitation of such a mixture with, as well as without, the addition of acid, would carry the metalliferous portions to the surface of the mixture and the gangue to the bottom; certainly those facts could not be successfully denied in view of the numerous references to the prior state of the art made in the opinion of this Court when this patent was last under consideration here and when the whole patent was by this Court held void as lacking invention (214 Fed. 100).

That judgment was, it is true, reversed by the Supreme Court (242 U. S. 261). In doing so, however, the Supreme Court held invalid Claims 9, 10, and 11 of the patent, each of which claims was for "a small quantity of oil." So that it is plain the appellees are not entitled to be protected in the use of "a small quantity of oil" of any kind which, as is obvious, is a wholly indefinite quantity.

In holding claims No. 1, 2, 3, 5, 6, 7, and 12 of the patent valid to the extent that it did, the Supreme Court, after pointing out in its opinion that there were many investigators at work in the field to which the process in suit related when the patentees came into it, and that it was while engaged in study of prior kindred processes that their discovery was made, said:

"While the evidence in the case makes it clear that they discovered the final step which converted experiment into solution, 'turned failure into success,' (the former patents having used so much oil as to make its cost prohibitive—our observation) (The Barbed Wire Patent, 143 U. S. 275), yet the investigations preceding were so informing that this final step was not a long one and the patent must be confined to the results obtained by the use of oil within the proportions often described in the testimony and in the claims of the patent as 'critical proportions,' 'amounting to a fraction of one per cent on the ore.'"

Amounting to a fraction of 1% on the ore is very far from saying amounting to *every* fraction of 1% on the ore; a fraction is one thing, *every* fraction is a very different thing. It is obvious, we think, that if the Supreme Court had meant to extend the scope of claims 1, 2, 3, 5, 6, 7, and 12 of the patent to *one per cent* of oil on the ore, as is here contended by the appellees, it would not have said anything about any *fraction* of 1%—certainly there would have been no necessity for doing so, and certainly the use of such specific language as it employed without a purpose cannot be justly imputed to that great tribunal.

That the "critical proportions" "amounting to a fraction of one per cent on the ore," so protected by the Supreme Court in its decision, does not include *every* fraction of 1% on the ore is, we think, very clearly shown by the same opinion where, after describing the prior state of the art, the Court said:

"Into this field of investigation at this state of its development came the patentees of the patent in suit.

They were experienced metallurgists of London, of inventive genius and with financial resources, and they entered upon an investigation of the processes of oil concentration of ores which was continued through several years, and consisted of a very extended series of experiments in which the quantities of oil, of water, and of acid used and the extent and character of the agitation of the mass under treatment resorted to, were varied to an almost unparalleled extent as to each factor and the results were carefully tabulated and interpreted. It was while pursuing a comprehensive investigation of this character, having, as the evidence shows, the special purpose in mind at the time to trace the effect on the results of the process of a reduction to the vanishing point of the quantity of oil used, that the discovery embodied in the patent in suit was made. The experimenters were working on the Cattermole 'metal-sinking process' as a basis when it was discovered that the granulation on which the process depended practically ceased when the oleic acid (oil) was reduced to about five-tenths of one per cent 'on the ore'. It was observed, however, that, as the amount of oleic acid was further reduced and the granulation diminished, there was an increase in the amount of 'float froth', which collected on the surface of the mass and that the production of this froth reached its maximum when about one-tenth of one per cent or slightly less 'on the ore' of oleic acid was used. This froth, on collection, was found to consist of air bubbles modified by the presence of the minute amount of oil used and holding in mechanical suspension between 70% and 80% of the total mineral content of the mass treated. It was promptly recognized by the patentees that this froth was not due to the liberation of gas in the mass treated by the action of the dilute acid used, and its formation was at once attributed in large part to the presence of the air introduced into the mixture by the agitation which had been resorted to to mix the oil with the particles of crushed ore, which air, in bubbles, attached itself to the mineral particles, slightly coated as they were with what was necessarily an infinitesimal amount of oil, and floated them to the surface. The extent of the agitation of the mass had been increased as the experiments proceeded until the "series of Gabbett mixers, fitted with the usual baffles, were speeded at from 1,000 to 1,100 revolutions per minute." A careful consideration of the record in this case convinces us that the facts with respect to the process of the patent in suit are not over-stated by the plaintiffs' witness, Adolf Liebman, an expert of learning and experience, when he says in substance: 'The present invention differs essentially from all previous results. It is true that oil is one of the substances used but it is used in quantities much smaller than was ever heard of, and it produces a result never obtained, before. The minerals are obtained in a froth of a peculiar character, consisting of air bubbles which in their covering film have the minerals embedded in such manner that they form a complete surface all over the bubbles. A remarkable fact with regard to this froth is that, although the very slight and easily destructible air bubbles are cov-

ered with a heavy mineral, yet the froth is stable and utterly different from any froth known before, being so permanent in character that I have personally seen it stand for twenty-four hours without any change having taken place. The simplicity of the operation, as compared with the prior attempts, is startling. All that has been done is to add a minute quantity of oil to the pulp to which acid may or may not be added, agitate for from two and one-half to ten minutes, and then after a few seconds collect from the surface the froth, which will contain a large percentage of the minerals present in the ore.' It is not necessary for us to go into a detailed examination of the process in suit to distinguish it from the processes of the patents relied on as anticipations, convinced as we are that the small amount of oil used makes it clear that the lifting force which separates the metallic particles of the pulp from the other substances of it is not to be found principally in the buoyancy of the oil used, as was the case in prior processes, but that this force is to be found, chiefly, in the buoyancy of the air bubbles introduced into the mixture by an agitation greater than and different from that which had been resorted to before and that this advance on the prior art and the resulting froth concentrate so different from the product of other processes make of it a patentable discovery as new and original as it has proved useful and economical."

Nothing, it seems to us, can be clearer from the foregoing quotations from the opinion of the Supreme Court, than that it did not intend to extend the monopoly of the patent in suit to the use of 1% of oil on the ore; for it, in effect, thereby distinctly declares and adjudges that the discovery of the appellee "experimenters" only rose to the dignity of *invention* when they ascertained that the desired results could be and were obtained by the use of five-tenths ($\frac{5}{10}$) of 1% of oil on the ore, with still better results as the quantity was reduced, to the vanishing point at less than one-tenth of 1%. The quantity of oil that gave birth to the invention—five-tenths ($\frac{5}{10}$) of 1% on the ore (at which point no more granulation exists)—to the lesser and extreme limit of the minute quantity (less than one-tenth of 1%)—at which the desired result ceases, are the "critical proportions" "amounting to a (*italic ours*) fraction of one per cent on the ore," to which the appellees' patent is "confined" by the Supreme Court, as we understand its opinion.

And that is just what appears from the present record was the contention of the present appellees before the Supreme Court on the argument of their appeal from the judgment of this court holding that there was *no invention* in what they did. For it is undisputed that on the argument of that appeal this colloquy occurred between two of the Justices and two of the attorneys for the then appellants and the present appellees:

"Mr. Justice McReynolds: I would like to ask you when in this process of reducing oil your invention came into existence.

"Mr. Kenyon: At about one-half of one per cent of oil.

"Mr. Justice McReynolds: Before you got to the one-half of one per cent did you have any invention?

"Mr. Kenyon: We were passing from the region of Cattermole, which was a distinct—

"Mr. Justice McReynolds: I want to know when your invention came into existence.

"Mr. Kenyon: This invention was not reached, I should say from those figures, until about 0.5, that is one-half of one per cent of oil was reached.

"Mr. Justice McReynolds: At one per cent you had no invention?

"Mr. Kenyon: No.

"Mr. Justice McReynolds: At one-half of one per cent you did have invention?

"Mr. Kenyon: It began to come, remote, but it began to come. At 0.3 of one per cent the flow vastly increased. At 0.1 of one per cent the flow again vastly increased.

"Mr. Justice McReynolds: When this flow is more than one-half of one per cent of oil it does not infringe?

"Mr. Kenyon: It does not infringe.

"Mr. Justice Pitney: What have you to say in answer to what Mr. Scott said the other day, to the effect that 1.8%, or perhaps more, of oil would give the same result with increased agitation?

"Mr. Williams: Absolutely no.

"Mr. Kenyon: It would not.

"Mr. Justice Pitney: I understood him to say so yesterday, and I supposed that there was something in the record to justify it.

"Mr. Kenyon: Nothing; that will be a part of my argument."

Inasmuch as it appears without dispute that the appellant company has never used in its process any oil in quantity as small as one-half of 1%, it results from the views above expressed that the judgment must be reversed and the case remanded with directions to the Court below to dismiss the bill at the complainants' cost, without regard to the question raised respecting the sufficiency of the disclaimer filed by the appellate company or to its resultant effect.

HUNT, Judge, concurring:

I will briefly state the ground upon which my concurrence rests:

The Supreme Court in sustaining the claims carefully noted those which were limited to a fraction of 1%, and the decision explicitly confined the patent to the results obtained by the use of oil within the proportions often described in the testimony and in the claims.

Claims 1, 2, and 3 use the language, "amounting to a fraction of one per cent on the ore."

Claims 5, 6, and 7 express amounts, percentages on the ore.

Claim 12 uses the words of limitation, "amounting to a fraction of one per cent of oil on the ore."

Claims 9, 10, and 11 make no reference to a fraction of 1%, but do contain the words, "a small quantity of oil."

The essence of the invention was in the use of this extremely small fraction of 1%, and the Supreme Court, while sustaining the fraction of 1% claims, held invalid the small quantity claims, 9, 10, 11, because they were too broad. No monopoly could be given on the use of a

small quantity of oil, for that was old. It was new, however, to avoid the use of larger quantities. The patent must be confined to the use of critical proportions.

Now, keeping in mind that by the decision the Court has limited the invention to the critical proportions often described by the testimony and in the claims, we naturally ask: What are the critical proportions described in the specifications? Page 1, line 79, of the specification says: "To this is added a very small proportion of oleic acid (say, from 0.02 per cent to 0.5 per cent on the weight of the ore)"; and on line 96 we have: "The minimum amount of oleic acid which can be used to effect the flotation of the mineral in the form of froth may be under 0.1 per cent of the ore, but this proportion has been found suitable and economical." We thus have given to us one-half of 1% or less as the critical proportion described—preferably one-tenth of 1% is to be used.

We also ask: What is the evidence wherein there is often described the "critical proportion?" A summary of it is that it is very nearly one-tenth of 1% or two-tenths of 1% as may be required for particular ore. All through the evidence it appears that minute and critical amounts of oil are to be used as necessary to make the process successful. From one pound of oil to the ton of ore (five hundredths of one per cent) to four pounds per ton (two-tenths of one per cent) were the limits in practical work as stated by witnesses.

Again, when counsel had the colloquy (quoted in the opinion of Judge Ross) with the Supreme Court, the guiding thought evident in the mind of the inquiring Justices was to stamp precision upon the point when *invention in the process* began to appear. With apparent definite purpose of meeting the interrogatories plaintiff told the Court that 'invention' began to come when in the descending uses of percentages of oil as small a quantity as five-tenths of one per cent was used, and was first present when three and two-tenths of one per cent was used. Of course, a Court should cautiously consider a response often quickly made by counsel in answer to questions put from the bench lest an injustice may follow by attaching undue weight to an isolated argumentative answer. But in this matter we are earnestly trying to gather the scope and accurate meaning of the expressed thought of the Court. We may therefore refer to the fact that the exact position of the plaintiff as to the invention was called for not once but twice, not generally nor indirectly, but positively, simply, and unequivocally. Hence, in the controversy as to the true interpretation of the opinion the questions put and answers given may be fairly resorted to, not as conclusive at all but as aids toward a better understanding of the statement of the limitations of the claims of the patent and of the definition of the invention included in its language.

Nor do I think there is ground for saying that discrimination was had between known oils—whether vegetable, mineral, or animal. To oily liquids which have a "preferential affinity to metalliferous matter" must the plaintiffs be held, and in using kerosene or fuel-oil defendants are but employing oils which the patents authorize the use of; and when defendants use propor-

tions beyond the critical ones of oil, not oleic acid, but other oils, they are not infringing. Oils doubtless vary in being adaptable for use. Some will probably secure more froth than others, and oil formulae may in their ingredients depend upon the particular ore to be treated and upon the economic relationship to the problem under solution. But the froth developed in using the minute quantities of oil is, I think, essentially of a character like the froth shown when different quantities of oil are used—the difference is largely by reason of a special quantity or kind of oil or the special extent of the agitation applied. The experiments made before us prove this.

In the Cattermole process the froth was held to be distinguishable from the froth produced in the patented process of the critical proportion of oil by the fact that certain remarkable and great results come from the use of the critical proportion which were not obtained when the quantity used in the Cattermole process was employed.

By using the critical proportion of oil, as defined, patentees get the maximum froth. They have discovered a process—not a froth—and the process is limited to the use of oil in the specified critical proportion.

The sequel of these views is that inasmuch as defendants keep out of the limits made for the plaintiff by the decision of the Supreme Court by using more than the critical proportion, they do not use plaintiff's process.

MORROW, Circuit Judge, concurring in part and dissenting in part:

I concur in the opinion of the majority of the Court that the decree should be reversed, but I do not concur in the direction that the bill be dismissed. I am of opinion that the use of an oil or oily liquid in defendants' separation process in a quantity not "amounting to more than a fraction of one per cent on the ore" is within the express terms of Claims 1, 2, 3, and 12 of plaintiffs' patent, and is an infringement of such patent. But I am of opinion that the use of oil or oily liquid in a quantity amounting to more than a fraction of 1% on the ore is not within the terms of Claims 1, 2, 3, and 12, and is therefore not an infringement upon plaintiffs' process and that a decree should be entered accordingly.

The direction of the Supreme Court in *Minerals Separation, Ltd., v. Hyde*, 242 U. S. 261, is that:

"the patent must be confined to the results obtained by the use of oil within the proportions often described in the testimony and in the claims of the patent as critical proportions, amounting to a fraction of one per cent on the ore".

The term 'critical proportions' is not used in the claims of the patent, but such proportions were described in the testimony in the Hyde case as the application of a small but exact quantity of oil to different ores and always within the range of treatment of "a fraction of one per cent on the ore," never to the treatment of different ores within the range of "one-half of one per cent" except in the use of oleic acid and that upon certain ores such as Broken Hill ores. The application of the term 'critical proportions' in the use of oil on ores generally within a

range of "one half of one per cent" was discovered by counsel for appellant in this case and so far as appears from the record was revealed to the public for the first time in this Court.

The colloquy between Mr. Justice McReynolds and Mr. Kenyon, counsel for appellant in the Supreme Court in the Hyde case referred to by Judge Ross in his opinion related to the use of oleic acid on Broken Hill ores concerning which I do not understand that there is any controversy. I think the direction of the Supreme Court that

"the patent must be confined to the results obtained by the use of oil within the proportions amounting to a fraction of one per cent on the ore"

means just what it says and that within such proportions the process described in the patent is held by the Supreme Court to be a valid discovery protected by the specifications and claims numbered 1, 2, 3, and 12. The Supreme Court does not say that the patent must be confined to the oleic acid claims (Claims 5, 6, and 7) nor does it say that the other claims of the patent must be confined to the use of oil in the fraction mentioned in those claims. Had the Supreme Court intended that the scope of the patent should be confined to the use of oil in the proportion not to exceed one half of 1% on the ore, it would certainly have said so in so many words and would not have left it to be inferred that the patent must be confined to results obtained by the use of oil in such proportions as are limited in Claims 5, 6, and 7. For what purpose does the Court hold Claims 1, 2, 3, and 12 valid? Manifestly because these claims provide for the use of oil in the proportions "amounting to a fraction of one per cent on the ore," that is to say, upon ores generally.

The specifications mentioned the fact that the ores were not all alike and that different ores may require the use of different proportions of oily material in order to secure the desired separation of metalliferous matter from the gangue by the production of a froth. The Supreme Court commenting upon this variation in the requirements of the process said:

"Such variation of treatment must be within the scope of the claims, and the certainty which the law requires in patents is not greater than is reasonable, having regard to their subject matter. The composition of ores varies infinitely, each one presenting its special problem, and it is obviously impossible to specify in a patent the precise treatment which would be most successful and economical in each case. The process is one for dealing with a large class of substances and the range of treatment within the terms of the claims, while leaving something to the skill of persons applying the invention, is clearly sufficiently definite to guide those skilled in the art of its successful application, as the evidence abundantly shows."

The use of oleic acid on Broken Hill ore was the oil and the ore of the discovery, and the proportion of the oil used is described in Claims 5, 6, and 7, but how about the use of other oils on other than Broken Hill ores? The proportions required for oleic acid on Broken Hill ores

had been determined by actual tests but other oils and other ores had not been fully tested and the application of the process might require a different proportion of oily material upon a different class of ores. To meet such a contingency, Claims 1, 2, 3, and 12 call for the use of an oil or oily liquid "amounting to the fraction of one per cent on the ore." Furthermore, in declaring Claims 9, 10, and 11 invalid, the Supreme Court clearly did so because such claims were not confined to the use of oil "amounting to a fraction of one per cent on the ore." The claim was for the use of "a small quantity of oil," which might be a quantity more than "a fraction of one per cent on the ore."

The validity of the other claims in controversy having been sustained upon their limitation of the use of oil within the proportion "amounting to a fraction of one per cent on the ore," it followed that Claims 9, 10, and 11 were held invalid because they were not so confined, and were therefore too broad. The disclaimer accordingly disclaims from Claims 9, 10, and 11 of the patent "any process of concentrating powdered ores excepting where the results obtained are the results obtained by the use of oil in a quantity amounting to a fraction of one per cent on the ore." Such language was strictly in accordance with the decision of the Supreme Court and, I think, a sufficient rejection of the excess from the invention claimed, leaving the patent in the form limited by the opinion of the Supreme Court.

With respect to the objection that the disclaimer was not filed in time, the mandate of the Supreme Court became effective January 13, 1917, decreeing the patent to be invalid as to Claims 9, 10, and 11, but valid as to the other claims in issue. On March 28, 1917, the plaintiffs filed their disclaimer, some time before the right to petition for a re-hearing in the Supreme Court had expired. Considering the importance of the procedure to be followed, the residence of the patentees in another country, and the consequent delay in communication, the date of filing was not unreasonably delayed.

PLATINUM PRODUCTION of the United States in 1917 was 605 oz. from placer mines. This is less than the sales in 1916 by 100 oz. Imports of crude platinum amounted to 31,921 oz., not counting the 21,000 oz. of Russian crude platinum that was received by the Government late in December last. During 1917, refiners made 33,000 oz. of platinum, 4800 oz. of paladium, 833 oz. of osmiridium, and 210 oz. of iridium, which can be called 'new metals.' Of this amount 7400 oz. probably originated from domestic materials. The saving of scrap platinum of all classes resulted in much larger recoveries of secondary platinum metals than in previous years, a total of 72,000 oz. being recovered, as compared with 48,000 oz. in 1916.

SPAIN has imposed restrictions upon the use of gasoline that are almost prohibitory. To supplement the diminished supply recourse is being had to the further development of alcohol for use in gasoline engines, including automobiles and trucks.

New Method of Determining Copper

By JAMES MOIR

My object in devising this process was to develop a method of doing without the large quantities of the expensive potassium iodide required in the ordinary accurate process for copper. For example, if high accuracy is required in determining the true percentage of copper in a 'pure' copper, about 4 gm. of the metal must be taken, involving the use of about 30 gm. of KI and 16 gm. of crystallized thiosulphate.

If the equations on which the ordinary process depends be studied, it will be seen that the net result of the addition of iodide and thiosulphate to cupric acetate is to produce an insoluble cuprous salt along with a soluble tetrathionate.

The net result is as if the equation were

It therefore struck me that the simple direct reaction between cupric salts and sodium thiosulphate would be worth investigating. A number of double copper-sodium thiosulphates were described by German authors 30 or 40 years ago, but it is probable that the whole of this work is wrong, and that the substances obtained were really tetrathionates and not thiosulphates. When equimolecular solutions of copper acetate (or copper sulphate) in the presence of acetic acid and sodium acetate and sodium thiosulphate are mixed, the mixture is greenish yellow and, in my opinion, consists mainly of soluble cuprous tetrathionate, but also contains a proportion of unchanged cupric thiosulphate.

Equation (5), which is a balanced reaction between cupric thiosulphate and cuprous tetrathionate, is perhaps more intelligible with separate ions.

The action being a balanced one is not suitable in itself for an analytical process; nevertheless it was obvious that the success of the old iodide method depended on the almost complete insolubility of the cuprous salt produced, otherwise the above balanced reaction would occur. This was confirmed on trying to replace iodide with bromide or chloride, the cuprous salts of which are fairly insoluble, when it was found that the reaction was incomplete. However, on trying sulpho-

cyanide (thiocyanate) as a substitute for iodide success was obtained. The above balanced reaction then goes entirely in the direction of cuprous tetrathionate because the cuprous ion is removed as insoluble CuSCN as fast as it is formed, and on filtration a colorless solution containing only $\text{Na}_2\text{S}_4\text{O}_6$ and excess KSCN and $\text{Na}_2\text{S}_2\text{O}_3$ is obtained, in which, under special conditions, the latter can be estimated with iodine even in the presence of sulphocyanide.

The analytical process suggested is therefore as follows: Dissolve the weighed sample in HNO_3 , and get it into the condition of very faintly acid cupric acetate, either by the old methods or by the quick process which I describe farther on. Add a slight excess of thiosulphate in known quantity (1 gm. copper requires 3.904 gm. crystallized thiosulphate, or about 158 cc. of N/10 thiosulphate) and immediately a sufficient excess of potassium sulpho-cyanide, equal to, say, $1\frac{1}{2}$ gm. per gramme of copper. The white precipitate of CuSCN is then to be filtered off, roughly washed, and rejected. Since it goes through every known variety of filter-paper, and since the solution cannot be heated (else the trace of acetic acid would act on the excess thiosulphate) it is necessary to add a quantity of pulped filter-paper before attempting to filter. This is made by boiling a loose-texture filter-paper in dilute caustic soda until disintegrated and neutralizing with acetic acid. On filtering, about 5 cc. will come through turbid before the pulp chokes the pores of the paper, after which a clear filtrate is obtained. As there is very little excess thiosulphate in this filtrate, any elaborate washing of the CuSCN precipitate is a waste of time.

To finish the analysis, the filtrate is first diluted to about a litre and then treated with 5 to 10 cc. concentrated pure H_2SO_4 (do not use HCl which, in a country with bright sunlight, always contains free chlorine) and a little starch-solution and titrated back with N/10 iodine, only a small quantity being required if the directions regarding thiosulphate have been followed. The calculation is merely:

$$\frac{\text{cc. true N/10 thiosulphate at beginning} - \text{cc. N/10 iodine}}{157.3} = \text{Cu}$$

The copper present is given in grammes by this equation, assuming 63.6 for its atomic weight. The filtrate must not be titrated with iodine without the high dilution and the mineral acid, otherwise iodine is absorbed by the excess KSCN present. Iodine does not apparently attack dilute HSCN .

If the approximate percentage of copper in the sample is totally unknown, the experiment must be done twice, first on a small sample of 0.1 gm., using 16 cc. of N/10 thiosulphate; and, second, repeating this, using thiosulphate equal to the thiosulphate minus iodine of the

*Abstract from Journal of C. M. M. Society of South Africa, November 1917.

[*The author used the symbol A for the acetic acid radical, which we have changed to Ac. — Editor]

first experiment. Thus if experiment 1 used 2.5 cc. iodine at the end, the correct thiosulphate for experiment 2 is at the rate of 135 cc. per gramme of material. This means that the method gives high results for copper (102 to 105% of the truth) when a large excess of thiosulphate has been used, but is sharply accurate when the thiosulphate is just in excess.

If extreme accuracy is required, 2 to 3 gm. of the sample must be taken, in which case it is better to weigh out the thiosulphate required. This is because 400 cc. of thiosulphate solution would have to be taken, and the factor of any thiosulphate solution is not generally known within 1 part in 500, besides which it varies with temperature. The following is a description of some of my results with the method:

1. Analysis of $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$. A sample of 0.2500 gm. in water and treated with sodium acetate and two drops HAc , then with 12.19 cc. $N/10$ thiosulphate of factor $0.985 = 12.01$ cc. true $N/10$ thiosulphate. At the end the diluted acid filtrate required 1.99 cc. $N/10$ iodine: the quantity of copper is

$$\frac{12.01 - 1.99}{157.3} = 0.0637 \text{ gm. (theoretical } 0.0636).$$

2. Pure copper (99.6% by iodide method). A sample of 0.1280 gm. dissolved: preliminary trial with 25 cc. thiosulphate used 4.4 iodine (giving $\text{Cu} = 102\%$). Second trial with 20.6 thiosulphate (corrected) used 0.54 iodine

$$\text{Cu} = \frac{20.06 \times 100}{157.3 \times 0.128} = 99.7\%.$$

Third trial with 20.5 thiosulphate used 0.40 iodine: $\text{Cu} = 99.85$. These discrepancies are due solely to the smallness of the sample taken, when one drop of reagent makes a difference of $\frac{1}{4}\%$ in the result for copper. If 1 gm. sample had been taken, an accuracy of 0.03% per drop could have been expected.

3. Electrolytic copper (over 99.9%). 0.1803 gm. dissolved: 29.3 cc. thiosulphate and 0.7 iodine used in first trial ($\text{Cu} = 100.7\%$): In second trial 28.60 thiosulphate (corrected) and 0.25 iodine: 28.35 difference or $\text{Cu} = 99.9\%$.

4. Copper-nickel-tin-lead alloy. After a preliminary trial, 24.66 cc. (corrected) thiosulphate used for 0.2315 sample: iodine used 0.78. $\text{Cu} = 65.6\%$. In this case the foreign metals were not separated and did not interfere, as analysis of this sample by standard methods gave $\text{Cu} = 65.8\%$.

Owing to the nature of my process scarcely any of the common metals (except iron) interferes. Only such metals could interfere as are capable of being reduced from their *ic* condition to their *ous* condition by dilute thiosulphate, the *ous* condition being then not oxidizable by iodine. So far as I can see, iron is the only metal that fulfils such conditions.

The quick process mentioned for getting the dissolved metal or ore into a condition for determining the copper depends on the little-appreciated fact that nitric acid is not an oxidizing-agent if nitrous acid is removed from it. According to the ionic theory, dilute pure nitric acid consists only of the ions H^+ and NO_3^- , the latter of which

has no tendency to part with its oxygen unless a strong reducing-agent is added.

The metal or ore is dissolved in a covered vessel with concentrated HNO_3 ; the solution is agitated for a minute or two to get rid of as much dissolved NO_2 as possible, diluted to 20 cc. and treated with $\frac{1}{2}$ gm. of urea (carbamide). After the effervescence has stopped the mixture is diluted to 50 cc. and boiled for 15 seconds. Thereupon caustic soda is added to near neutrality, followed by 2 or 3 gm. of solid sodium acetate. The analysis can then be proceeded with.

The destruction of the nitrous acid is explained by the equation:

MOLYBDENUM ores are usually purchased on the basis of the molybdenum sulphide contained. Wulfenite is usually bought on the basis of its metallic content, or on the molybdic oxide, MoO_3 , contained. Ferro-molybdenum is usually offered on the basis of its metallic content. In the United States and Canada, payments are calculated on the short ton of 2000 lb., and the quotations for MoS_2 are based on the unit of 20 lb. In Great Britain, and many parts of the British Empire, except Canada, the long ton of 2240 lb. is used, and the unit quotation is based on a quantity of 22.4 lb. The schedules on which payments are made are somewhat detailed. Buyers of molybdenite ores that contain from 0.5 to 3.0% molybdenite, have paid for 70 to 92% of the sulphide contained, after deducting a suitable treatment-charge. The middling product and concentrate containing from 3 to 85% molybdenite, and crude ore containing from 2 to 80% molybdenite, are purchased, the price paid for the lowest grade being 20 to 35% less than for the highest grade. Penalties are usually imposed for bismuth and copper. Ferro-alloy makers will purchase ore or concentrate which contains 65% molybdenite, provided the iron does not exceed 10%.

NEW EXPORT DUTIES on minerals from Peru are as follows: On metallic silver in any form, \$1.50 U. S. per kilogramme; and for sulphides or precipitates, one-fourth that of the metal. On copper, \$1.25 per short ton, plus 10% of the excess of the current price at New York, over the minimum valuation of 13 cents per pound. Gold in copper and smelter products in excess of 6 grammes per ton is increased from \$9.60 to \$48 per kilogramme, with a refund if an equivalent amount is imported. Vanadium ores and concentrates are dutiable at \$4.80 per metric ton, when the vanadic-acid content is from 18 to 20%, with an increase of \$2.40 per ton for each additional 5 units of contents above 20%. For tungsten the rate is \$4.80 per metric ton when the price in New York is not less than \$20 per unit. The excess value of the exported product is subject to a tax of 10%, based upon an assumed content of 50% of tungsten. Molybdenum ores and concentrates are dutiable at \$9.60 per ton without qualification or surcharge. Formerly the duty on all of these ores and concentrates was fixed at \$4.80 per ton without regard to value.

Zinc From Broken Hill

By courtesy of Mr. G. D. Delprat, manager for the Broken Hill Proprietary Co., at Broken Hill, New South Wales, we are enabled to publish a photograph of the first 50 tons of zinc concentrate produced at Broken Hill by means of flotation without the use of oil by the Delprat process in May 1903. This same process is still in use; it has helped to produce 836,343 tons of zinc concentrate up to March 6, 1918. The photograph shows a

distinct and persistent rose color. The reaction is more sensitive if the alkaline solution is boiled and allowed to cool before adding the oxalate and AcOH. The reaction does not occur if a mineral acid is used or if $(\text{NH}_4)_2\text{SO}_4$, for example, is substituted for $(\text{NH}_4)_2\text{C}_2\text{O}_4$. The presence of the oxalate is indispensable to secure a distinct reaction. Salts of other metals do not interfere, except that Cu, Fe, Ni, Co, Pt, Au, and Cr, which give colored solutions, mask the reaction if present in considerable amount. It is desirable, nevertheless, to separate the other metals. A pronounced color was obtained with one

THE FIRST SHIPMENT OF ZINC CONCENTRATE PRODUCED BY OIL-LESS FLOTATION AT BROKEN HILL.

group of notable men, most of whom have made a name for themselves as inventors and patentees of various modifications of the flotation process. In the Delprat process a hot solution of acid salt-cake is added to the crushed ore as it is fed upon a pan having a sloping bottom heated by a Bunsen burner, the sulphides being raised to the surface by the bubbles of carbon-dioxide gas and air generated by chemical action and heat. We have asked Mr. Delprat to send us a description of his process as improved by experience in the mill.

MANGANESE, even in minute quantities in solution, may be detected as follows, according to H. S. Paine, following V. Maerl (Boll. Chim. Farm. 56, p. 377, 1917). Render the solution slightly alkaline, and shake with several drops of an alkali oxalate solution, and finally with a few drops of AcOH. The liquid assumes a dis-

drop of a 0.1% solution without previous boiling. The reaction may be facilitated by adding one to two drops of H_2O_2 before making the solution alkaline.

During 1917 the low-grade mill of the Nipissing Mining Co., at Cobalt, Ontario, treated 73,015 tons of ore assaying 31.13 oz. of silver per ton. In extracting 1,932,831 oz., equal to 80.64%, the cyanide plant used the following supplies:

	Total lb.	Cost per lb.	Total cost	Lb. per ton	Cost per ton
Sodium cyanide	338,024	\$0.3270	\$108,406	4.6290	\$1.4847
Caustic soda	61,867	0.0390	2,423	0.8170	0.0332
Lime	367,125	0.0046	1,697	5.0290	0.0232

Manganese Requirements

The needs of the steel industry of the United States are about 800,000 tons of manganese per year, corresponding to 310,000 tons of ferro-manganese. In 1917 our imports of manganese ore were 629,972 tons, the remainder being supplied chiefly by our own mines, working at full capacity. Our 85% of the 1917 imports probably came from Brazil. The output of standard ferro-manganese in this country last year exceeded all records, being 257,834 gross tons, or nearly 50,000 tons in excess of the previous high record of 208,389 tons in 1916. The following table, based on the monthly blast-furnace reports of 'The Iron Age,' gives the output of ferro-manganese and spiegeleisen in the United States in the last six years, stated in gross tons:

	Ferro-manganese	Spiegel-eisen	Total	Average per month
1917	257,842	188,852	446,686	37,222
1916	208,389	197,518	405,807	33,817
1915	146,542	93,282	239,824	19,985
1914	106,083	100,365	206,448	17,204
1913	119,495	126,081	245,576	20,464
1912	125,378	119,506	244,884	20,407

While the expansion in 1917 was not as great as that in 1916, it was large. The shrinking in the spiegeleisen output was unexpected, and while the decline is not large, the total is twice that of 1915. Details of the production, imports and exports of ferro-manganese for 1917 in gross tons were:

	Output	Imports	Exports
Total	257,853	45,381	5,468
Monthly average, 1917	21,486	3,703
Monthly average, 1916	18,461	7,577
Monthly average, 1915	12,021	4,605
Monthly average, 1913	9,958	10,672

These figures show how the domestic output has been steadily climbing. In the last half of 1917 the monthly output was 23,000 tons, or almost double that for 1915, and over twice that of 1912, which was the pre-War record. The significant fact is the dwindling of the imports from England. In 1917 they were at the rate of 3703 tons per month, declining in the last half to 2464 tons per month. Soon after the entrance of the United States into the War, it was officially estimated that the steel industry of the country needed 28,000 tons per month of ferro-manganese. The average available supply for 1917 was 25,032 tons per month.

The increased demand for manganiferous steel products, coupled with the cutting off of important sources of supply, has materially affected prices. From 1900 to 1914, 49% ore sold for from 23 to 30c. per unit. In 1916 it rose to 45 to 65c.; in 1917, it reached \$1, and in some cases has gone as high as \$1.20 to \$1.50 per unit. Stated otherwise, the prices paid for the ordinary run of ores varied from about \$8 to \$14 per long ton before the War, while in recent months similar ores have brought from \$40 to \$75. Ferro-manganese, which before the War sold at about \$40 per ton, has recently been quoted at about \$175. Spiegel, which averaged

about \$25 in 1914, sold at about \$65 last year. The fundamental war problem involving manganese is how to satisfy the greatly increased demand. The United States can get practically no manganese ore from contiguous countries. The ore must be brought chiefly from distant lands by marine transportation, at a time when all available ship-tonnage is of the utmost importance for the transportation of men, munitions, and food to Europe. A ship can make several round trips to Europe in the time it can make one round trip for a cargo of ore to Brazil or India. The fleet of 20 or 30 ships that had been engaged in this trade during the last year was an object of great concern to the Government authorities and to the Shipping Board.

The main domestic sources of supply have been the nodular and pocket ores of Virginia, Georgia, and Arkansas, and the lenses and vein deposits of California. In none of these places are there large bodies of high-grade ore that can be rapidly worked. While no close estimate can be made, it seems likely that, with the probable increased demand for 1918, with steel practice remaining the same, even under the stimulus of high prices and favorable governmental action, the production of high-grade ore could not be made to exceed 20% of the manganese content needed for ferro-manganese.

Low-grade ores, suitable for the production of the low-grade alloys, are more widely spread, and in larger masses. The most important manganiferous iron-ore deposits are in the Lake Superior iron region. Harder and Johnston have recently described important areas in the Cuyuna district, Minnesota, where, associated with ferruginous cherts and shales, large bodies of iron ore frequently carry manganese in quantities varying from 1 to 35%. Several million tons appear to be available. The Appalachian belt, Arkansas, and California, and adjoining States, also carry lower-grade ores, associated with those of higher grade. Except in California, these are usually manganiferous iron ores. In California the iron content is usually low, and silica high.

Since the beginning of the War, a start has been made in utilizing the ores in Montana, Colorado, Utah, Nevada, Arizona, and New Mexico. The manganese varies from a trace up to 30 or 40%, and there is apparently a large supply that would average 10 to 15%. Another source of manganese is the residuum from the working of the manganese-zinc ores of New Jersey. In 1915 this amounted to 159,318 tons, averaging 14% manganese.

Another line of attack is being directed toward a change in metallurgical practice. Experiments are being tried in some of the steel plants in the substitution of spiegel for ferro-manganese in the open-hearth process. A careful study of the field indicates that the steel industry can really get along with less manganese, or can use alloys in which other more available material is in part substituted for it. Such changes will lessen the demand for ore an equal amount, but as an essential element of the War there will be a continuous demand. In so far as such changes or substitutions are made the demand for high-grade ore or for manganese itself will be lessened.

REVIEW OF MINING

NEW YORK

American Institute of Mining Engineers: Its Title.

The proposal to change the name of the American Institute of Mining Engineers to the American Institute of Mining and Metallurgy has aroused considerable interest. The current bulletin contains much information in this connection. It is explained that the proposal was previously abandoned, without the taking of a vote, in 1912, in order to permit the paying of attention to matters of more importance. The need for including reference to metallurgy in the designation of the Society is emphasized by the fact that more than two-thirds of all the papers found in the Transactions during the past three years referred to metallurgical practice and advance, which is sufficient evidence of the importance of this phase of metal production. It also has been pointed out that a large number of metallurgists, many of whom are recognized authorities, are unwilling to join a society that would confer upon them the title of 'mining engineer,' realizing that this would be a misnomer, besides being of no professional value to them. Many of these, as the secretary of the Institute states, have never seen a mine, and the majority have little or no interest in mining engineering, in itself considered.

During a trip by officers of the Institute in March and April through some of the Western States the question of changing the name of the Institute was raised and comment invited. The Chicago section appeared to be unanimously in favor of the change. The members of the Boston section either withheld comment or favored the scheme. At Salt Lake City there was a majority in favor of the new name. At Anaconda there was unanimous approval. The Columbia section made no objection. At Puget Sound the idea was favorably received and without opposition. The St. Louis section was unanimously in favor of the alteration.

Although the results recorded do not represent the opinions of all the members connected with the various sections referred to, the conclusion may be reached that, as the straw-vote shows, a large number of members of the Institute would welcome a change which would tend to enhance their professional status as metallurgists; and that the great majority of members would favor the scheme as a more satisfactory method of designating the society. In view of the apparent unanimity of opinion elsewhere it is strange to note that the Colorado section was apparently opposed to the change for several reasons. In the first place, it was stated that the old name had been in satisfactory use for 47 years, and that this was sufficient cause for its retention. How the sponsors of this argument can ignore the immense progress in metallurgical advance during this period, the increasing interest being taken in metallurgical practice, and the far-reaching importance of metallurgical research, is a matter for surprise. The second argument against the change was that the word 'metallurgy' is not understood by the public, which is unable even to spell it. Assuming that the general educational standard is as low as suggested, which is open to question, the fact remains that the public has no interest or influence in the choosing of a suitable or fitting designation for a professional society. The members themselves are the best judges.

If one of the general public wished expert advice on some metallurgical process he would be little likely to seek a consultant from among the members of a society of 'mining engineers.' The arguments of the Colorado section can carry no weight; they are altogether unconvincing. The proposed change would not affect the status of the mining engineer in any way; it would merely accord a just recognition to the metallurgist, who has done so much to make the Institute a success, and whose endeavors have contributed to the present magnitude of the metal-mining industry. The final argument against the change, made at the Colorado meeting, was that metallurgists are no more entitled to be represented in the Institute's name than geologists, chemists, or assayers. The objection indicates a misapprehension of the facts. The A. I. M. E. is not intended as a suitable professional society to include persons interested only in pure chemistry or geology. If his specialty is metallurgical chemistry he will doubtless voice no objection to being a member of an institute of mining and metallurgy. A copper metallurgist who disclaimed a knowledge of physical chemistry would be an anomaly. A gold metallurgist who knew nothing about technical chemistry would be lacking in the fundamentals of his art. Metallurgical chemists—and these are the only types of chemists the Institute includes—will be content with the new name. Assaying is also a phase of metallurgical work, and few assayers would object to being classed under 'metallurgists'; but, in company with the metallurgical chemists, they realize that the designation 'mining engineer' does not apply to them and, what is more, is not desired. The importance of mining geology is recognized, but there are few geologists who would disclaim the title 'mining engineer,' or would suggest that they represent a fraction of the Institute members claiming prior right to a specific designation in the title. Statistics show the predominant interest to be, respectively, mining and metallurgy; and a society named as now proposed may well include both mining geologists and metallurgical chemists.

The objections from Colorado savor of a desire to revive the exploded fallacy that the profession consists of mining engineers only. This contention pretends to ignore the fact that the increase in metal production during the past 30 years owes much to the skill and ability of specialists who are not mining engineers. Metallurgical progress since 1887 has marked an advance unparalleled in any other similar period in the world's history; and metallurgists claim recognition of the fact. The change in the title of the Institute will be welcomed by the large number of specialists who have added their writings to the Transactions. It will not be deemed an intrusion by those members who are more particularly interested in mining rather than metallurgy and who will be generous enough to agree with the late president of the Institution of Mining and Metallurgy, of London, when he said that "the fact was often overlooked that the metallurgist was a specialist whom they, as mining engineers, gladly recognized as being no less important to the success of mining enterprise than themselves."

Of building stones quarried in New York State, sandstone leads in value, followed by granite and marble.

CRIPPLE CREEK, COLORADO

Drainage-Tunnel.—Power for the Golden Cycle.—Leasing-Profits.

The Roosevelt drainage-tunnel was advanced 100 ft. during April; the Cresson drift from the tunnel-level, on the Funeral dike, 212 ft.; and the Portland drift toward the main or No. 2 shaft 198 ft.; a total of 510 ft. of work at the tunnel-level. The flow from the portal has fallen to 3055 gal. per minute.

The State Utility Commission having rejected the petition of the Golden Cycle company for a restoration of the original rate charged by the Colorado Springs Light, Heat & Power Co., the Golden Cycle has decided to construct an electric power-plant costing \$200,000. The site has been selected near the company's Pikeview coal mine near Colorado Springs. The plant will furnish power and light to the mill and to the mines of the Pikes Peak Fuel Co., controlled by the Golden Cycle at Pikeview.

Net profits from the Hayes lease on No. 11 level of the Vindicator Consolidated for April exceeded \$30,000. This is remarkable, few, if any, leases of the district have earned such profits in so short a time. The ore-shoot being worked is on the middle vein of the Vindicator system. The ore as broken is from 12 to 30 ft. wide, and that shipped was taken out by driving only. No stoping has been done. The drift on the ore is 70 ft. long, and coarse rock has averaged close to 2 oz. gold per ton, and screenings over 5 oz. The last car of screenings settled for 5.24 oz. The lease is worked on the split-check system, the owning company receiving one-half, or \$15,000; A. I. Hayes of Victor, Peter Cartee of Goldfield (Colorado), and W. M. Craig of Cripple Creek dividing the remainder according to their several interests. With stoping started the output and profits are expected to increase.

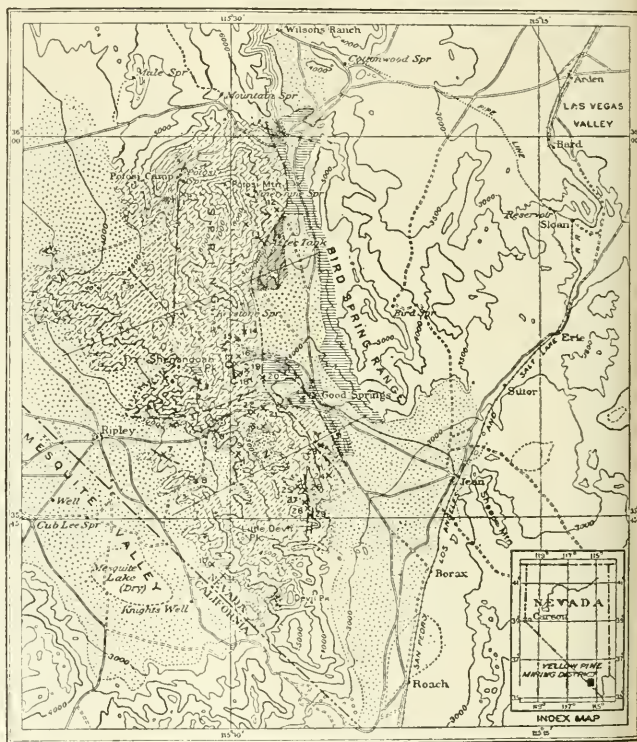

The United Gold Mines Co. in April shipped 3000 tons of ore worth \$50,000 from its Bonanza, Trail, Wild Horse, and W. P. H. mines.

GOODSPRINGS, NEVADA

General Description of the District.

Yellow Pine mining district, Clark county, is described by Fred A. Hale Jr. in Bulletin 134 (February 1918), of the A. I. M. E. The region has an area of 400 square miles. Principal shipping point is Jean on the Salt Lake Route. Goodsprings is the centre. Water is not abundant, but wells have been opened at Goodsprings, Mesquite valley, and springs on Mt. Olcott. Climate is equable. Mormons discovered lead ore in 1852. Gold was found in the early 'nineties. Zinc was recognized in 1906, and the opening of the Salt Lake Route added impetus to production. The lead-zinc oxidized ores were complex, and smelter returns were disappointing. By 1910 the Yellow Pine Mining Co. had evolved a separating process, and erected a 100-ton mill that has worked since. In 1911 this company constructed a narrow-gauge line, which improved transportation facilities in the district. Other mills have been erected, and production steadily increased. Output of the district was 76,382,543 lb. zinc, 26,-492,680 lb. lead, 1,327,390 lb. copper, 739,-

980 oz. silver, and \$206,684 gold to the end of 1915, valued at \$7,847,332; and to end of 1917 approximately \$12,000,-000. Principal ore deposits may be divided into two general classes, namely: (1) oxidized lead-zinc, and (2) copper-gold; some of the latter carrying platinum metals. Lead-zinc deposits have yielded most of the ore. Orebodies are essentially of the replacement type, and are apparently confined to one limestone stratum, although frequent step-faulting, with considerable throw, gives the appearance of separate orebodies. In the Yellow Pine mine ore at depth (900 ft.) is as thoroughly oxidized as close to surface, no sulphide of zinc having been found, and no increase in the amount of lead sulphide. Down to 950 ft. there is no water. The copper-gold deposits apparently have no stratigraphic relation to the lead-zinc deposits, although they are determined by presence of fracture-zones. Dry concentration is satisfactory for the 10% lead and 30% zinc ores, but treatment of low-grade ore has not been solved.

MAP OF YELLOW PINE DISTRICT, NEVADA (AFTER J. J. HILL, U. S. G. S.)

ARIZONA

Bisbee.—The Denn-Arizona Copper Co. in 1917 produced 98,932 lb. copper, 858 oz. silver, and 50 oz. gold from 1477 tons of ore. This realized \$17,539 at the smelter. New development cost \$179,648 net, that is, from May 1 to December 31, 1917, the period of operation. To raise money the capital was increased from 350,000 to 500,000 shares of \$10 each, 50,000 being offered to holders of outstanding shares at the ratio of 1/2 of one new share for 1 of outstanding shares, making 49,968 available. Of these, 47,737 were taken up, amounting to \$477,370. All indebtedness has been paid, leaving \$191,026 on hand to meet current accounts. By June 1918 it is hoped that shipments will pay expenses. Resumption of work late in April 1917 resulted in re-timbering the shaft, re-building the head-frame, repairing the 1000, 1100, 1250, and 1350-ft. stations, cutting a new station on south side of 1250-ft. level, also at 1450-ft., and doing 3392 ft. of development from 1100 to 1450 ft. depth. Pay-ore (oxide) in small quantities was exposed on the four levels. New equipment and construction cost \$38,973, and resumption repairs \$81,057. L. C. Shtuck is general manager.

Shattuck-Arizona company in the first quarter of 1918 made a profit of \$185,518, compared with \$696,099 in the same period of 1917. Copper ore smelted amounted to 24,272 tons, and lead ore 501 tons. These yielded 2,717,075 lb. copper, 217,643 lb. lead, 267 oz. gold, and 27,618 oz. silver. New development covered 4263 ft. Between the 800 and 900-ft. level a good body of 41% pyritic copper ore was exposed. Construction of the lead concentrator is well advanced.

Chloride.—The Tuckahoe mine has been equipped with electric pumps and will be unwatered at once.

The Bella Union last week shipped the first bullion that has been sent out from the Chloride district for a long time.

The 1700-ft. tunnel on the 400-ft. level of the Copper Age is nearing completion. This property is said to have 250,000 tons of ore blocked out. The mill is expected to be started by the end of May.

This important mining district was described briefly by Rush T. Sill of Los Angeles in February 'Mining and Oil Bulletin.' Chloride is 26 miles north of Kingman on the Santa Fe railroad, and is on the western border of the Cerbat mountains, which are high and rugged. The district covers an irregular area about 6 miles diameter. Veins occur as two systems, one striking north 10 to 30° west, the other more or less associated with younger intrusions of granite-porphry. In some, the ore is associated with dikes of andesite and rhyolite. Outcrops are generally prominent, consisting of reddish-brown quartz and manganese. The north-south veins are the most important. They carry gold, silver, lead, zinc, iron, and a little copper, lead and zinc predominating. At the present time sulphide ores are utilized principally, but the rich secondary ores, containing hornsilver, native silver, and in some places ruby silver, furnished the bulk of the production in early days. The number of deposits is large, and owing to the fact that work was generally abandoned when the lean primary ores were encountered, the area contains a large number of small mines that may be capable of further production.

Principal mines of the district are on this north-south system, the Tennessee, Schuylkill, Elkhart, Payroll, Emerson, Minnesota-Conner, Hidden Treasure, Golconda, and others. Most important of these is the Tennessee, which has been worked for almost 25 years, and has a production estimated at \$20,000,000. The Schuylkill mine, now being worked by Burke, Garbutt, and others, has been developed to 800 ft. Good bodies of ore have been developed. Since the owners of the Tennessee mine refused to extend the time for payments to the U. S. Smelting, Refining & Mining Co., the Schuylkill company has made arrangements to take over the Tennessee and its work in conjunction with the Schuylkill, developing the latter from the 1400-ft. level of the former. The Tennessee was being worked at a depth of 1600 ft. Orebodies are large; in some places 22 ft. of solid galena and sphalerite was mined.

Elkhart mine, adjoining the Schuylkill mine on the north, is a producer of early days. The mine has produced from the surface to the 500-ft. level. Ore is similar to that of the Tennessee, and there is every reason to believe, from the size of the orebodies on the 500-ft. level, that ore will be found at a much greater depth.

Minnesota-Conner is another famous producer of high-grade ores, which was operated some years ago. It has been developed to 700 ft., and is equipped with an extensive milling plant.

Golconda has been developed to 1100 ft., and has produced \$10,000,000. It was equipped with a modern mill, which burned in the latter part of 1917, causing a shut-down.

The east-west veins have been developed most extensively on the Flat to the west of Chloride. This is open country on the edge of the Sacramento valley. The principal mines developed on the east-west silver-bearing veins are the Towne, Merrimac, Diana, Rattlesnake, Tuckahoe, Midnight, and a number of fair prospects upon which there has been a small amount of development. The first named yielded \$1,000,000 between 1882 and 1906. It might be said that little attention has been given these east-west veins.

The Chloride district has produced many millions in gold, silver, lead, and zinc ores. With the high price of lead and zinc that have prevailed for the last two or three years, the camp has been active; but with the drop in prices, many of the smaller mines have had to suspend operations. There is a possibility, however, that with the high price of silver, some of the mines on the Flat will be equipped and reopened, which will add to the life and production of the district.

Humboldt.—On June 1 Consolidated Arizona Smelting Co. pays 15c. per share.

Jerome.—At present there are three producing and twelve developing companies in this district, employing 3500 men. The monthly output is over 13,000,000 lb. of copper.

United Verde Extension's new smelter may be blown-in about the middle of June. The 425-ft. stack is practically finished.

Verde Combination has done several thousand feet of work on its 700-ft. level, where a leached zone was opened. Sinking to 1000 ft. is in progress.

Calumet & Jerome is driving a long cross-cut south-west

from its 600-ft. shaft to explore a formation exposed in an adit driven above the shaft.

The Shea mine is considered one of the best prospects in the district. At a depth of 350 ft. in the incline shaft a vein is being followed. Car samples assay 1.2% copper, 28 oz. silver, and \$6 gold per ton.

The Grand Island company is drilling to 800 ft. to cut a vein exposed by the 208-ft. shaft.

In the Pittsburgh-Jerome some good ground has been opened on the 500-ft. level. Five drifts are being driven. About 35 men are employed.

Jerome Verde has resumed work at its Maintop claim, which yielded 1600 tons of 9% ore last year. The work now being done is on the 1400-ft. level from the United Verde Extension, 200 ft. below the point from which the ore was taken. A raise will be run to connect these two levels. The company is also developing from the 1405-ft. level of the Columbia shaft, both by diamond-drill and drifts.

Results at the Dorothy May shaft and Gorge tunnel of the Green Monster are encouraging, and it has been decided to sink 300 ft. deeper.

Miami.—Liberty Bond subscriptions taken by this centre were as follows:

Inspiration Consolidated Copper Co.	\$1,000,000
Miami Copper Co.	50,000
Employees of—	
Inspiration	119,750
Miami	97,000
International smelter	32,000

Total for district.....\$1,299,250

ARKANSAS

Fort Smith.—The Fort Smith Spelter Co. has closed its smelter and rolling-mill indefinitely. This is considered peculiar, as there is said to be a big demand for sheet-zinc.

CALIFORNIA

The California State Mining Bureau, at the Ferry building, San Francisco, has prepared a topographical and geological map of Inyo county. It shows in detail the situation of ore deposits, geological structure of the region, towns, post-offices, springs, wells, railroads, wagon-roads, and trails. This area is one of the most interesting geographically, as well as from a mining standpoint, of any similar area in the West. The county contains 10,019 square miles, with an estimated population of 7500—less than one inhabitant to a square mile. It is noted because of the fact that within its borders are both the highest and the lowest points in the United States; the former, Mt. Whitney, has an elevation of 14,501 ft., and almost within sight of this mountain is a point in Death Valley which is 280 ft. below sea-level. This sparsely settled and rugged district produced last year minerals valued at approximately \$5,000,000. A large proportion of the borax production of the United States comes from the county. Its mountains produce gold, silver, copper, lead, zinc, and other metals; and from its old lake-beds are derived soda, salt, nitre, and similar substances. The map mentioned has been lithographed in 17 colors, and is offered for sale at 60c., which merely covers the cost of printing. A report describing in detail the mineral resources of this county has also been recently published by the Bureau, and both map and report may be obtained for \$1.25.

Bakersfield.—Oil production of the State in April totaled 276,471 bbl. daily, an increase of 9000 bbl. over March. There were 8248 producing wells, 48 new ones being completed. Stocks on April 30 were 30,502,447 bbl. These have dropped 1,948,018 bbl. in 4 months.

Grass Valley.—Up to March 1, 1918, the Golden Center

mine here has produced gold worth \$355,224. During five years over 11,000 ft. of development has been done. C. A. Brockington has retired from the management in favor of A. Cadogan. The former was largely responsible for reopening this mine.

Oroville.—The Pacific Gold Dredging Co. has ceased operations in this field, but will maintain its office here to manage the Butte Creek, Yuba River, and Trinity River boats.

Plymouth.—The Plymouth Consolidated Gold Mines reports as follows, covering operations during 1917:

Sales of gold and concentrates, and sundries, totaled \$686,000. Operations in California cost \$433,000. London charges, American taxes, depreciation, etc., amounted to \$82,000. The profit was therefore \$171,000. Adding the balance of \$53,000 from 1916, there was available

MAP SHOWING PRINCIPAL CENTRES IN AMADOR COUNTY, CAL.

\$224,000. Two dividends of 24c. each totaled \$115,000. After deducting income-tax, the balance carried forward to 1918 was \$86,000. Development totaled 5017 ft. The main shaft was deepened 152 ft. on the incline, and at 2600 ft. a station and ore-bin were excavated. The most important result was the discovery of the north foot-wall ore-shoot on the 2150 and 2300-ft. levels. On the former there is 177 ft. of ore, 48 in. wide, averaging \$6.24 per ton. A rise above this disclosed 57 in. of equal value. At 2300 ft. there is 140 ft. of \$8.24 ore across 96 in. The widest part is 26 ft. across. On the 2000-ft. level prospects are good. On the bottom level—2600 ft.—the main east cross-cut showed 60 in. of \$4.44 ore, the south drift 39 in. of \$6.96 ore, and the north foot-wall drift 12 in. worth \$4.44 for 15 ft., then 72 in. worth \$2.76 for 56 ft. Ten levels contributed to the output of 127,750 tons. The mill extracted \$3.72 by amalgamation and \$1.56 by concentration, a total of \$5.28, equal to \$6.37% on the average of \$6.12. Residue assayed 84c. per ton. The bullion yield was 32,795 oz. gold and 7688 oz. silver. As the tailing assayed higher than before, due to a change in nature of the ore, two Hardinge mills and more copper plates were added. Costs were 46c. for development, \$2 for mining, 38c. for milling, 24c. for bullion and concentrate expenses, and 31c. for maintenance and general, a total of \$3.39 per ton. J. F. Parks is superintendent.

Sonora.—The Hope Mines Development Co. has issued a statement wherein it appears that its revenue in 1917 amounted to \$90,682, of which \$74,352 was from bullion and ore. Expenses were \$90,682, including \$4698 on dividend account. George Weston is manager.

Redding.—Lawrence Gardella's dredge No. 2 on Clear creek has been started. This is the third boat near here.

COLORADO

Cripple Creek.—Report of the Cripple Creek Central Railway, holding company for the Cripple Creek & Colorado Springs Railroad Co. and the Midland Terminal Railway Co., covering 1917 and the last half of 1916, shows that the Cripple Creek Central paid \$270,000 in dividends last year and \$135,000 in the last half of 1916. Cash at December 31 last was \$531,088, an increase of \$120,000 during the year. The freight carried was 151,590 tons less in 1917 than in 1916. Operating expenses for 1917 was \$146,661 less.

Vindicator Consolidated reports a profit of \$125,000 for the first quarter of 1917. Cash balance on April 19 was \$160,887, plus \$20,000 for ore in transit. Development was stopped for good in the lower levels. Considerable work done showed that it was useless to proceed farther. Operations for the period showed a substantial improvement over those for the last quarter of 1917. Ore coming from stopes was of much better average grade, the new ore-house is a distinct success, and the mill is making a moderate profit. A substantial improvement has also occurred in lease operations over conditions existing last fall. More lessees are at work, and several of them have opened excellent ore, from which the company is deriving substantial royalties.

Idaho Springs.—At the west end of Clear Creek county between Georgetown and Silver Plume the Wide West Mining Co. has laid 2700 ft. of the Hall tunnel with 46-lb. rails. The heading is to be driven 500 ft. farther. The Dorothy vein is being opened for extraction of ore. J. Terry is manager of this company, whose prospects are considered good.

Leadville.—Manganese ore exposed on the 465-ft. level of the Bohn shaft, right in town, is 13,500 tons; but the probable production is several times this amount. In April 500 tons shipped assayed from 34 to 37% Mn.

Nederland.—Rich silver-lead ore has been opened in the Conger Chief mine.

The Royal Gem company is starting work on a large scale.

The Bismark shows rich lead-silver-copper ore.

Lakewood is the busiest tungsten district of this field at present. The Primos company is working at full capacity.

At Cold Springs the Wolf-Tongue company is mining large quantities of tungsten ore. The mill at Nederland is working full time.

Silverton.—The aerial tramway at the Lackawanna mine is ready for operation. It is of the Bleichert type, 3700 ft. long. The company expects to employ 30 men at the mine and at the Silver Lake custom mill, which has been leased. One hundred tons per day will be treated on two shifts. C. B. Sheehan is manager of the property, which the D. L. & W. Co. apparently intends to develop into a year-round shipper. Recently rich ore was uncovered, 15 to 18 ft. thick, extending to a depth of several hundred feet. Immediate prospects seem bright.

The Telescope Mining Co. has 8 men clearing tunnels, preparing for the coming season. Ore carries lead and silver.

IDAHO

Hailey.—The North Star and Independence mills of the Federal M. & S. Co. have been re-modeled and put into service again. The former dresses a lead-silver-zinc ore, the latter lead-silver ore. These mines are a mile apart in a direct line.

Moscow.—In co-operation with the U. S. Bureau of Mines, the University of Idaho, through the generosity of the mine-owners of the State, offers in the School of Mines a number of fellowships in metallurgy. These are open to college graduates who have had good training in chemistry and

metallurgy, and who are qualified to undertake research work. The income of each fellowship is \$720 per year of 12 months beginning July 1, 1918. Fellows will register as students in the university and become candidates for the degree of master of science in mining or metallurgy (unless this or an equivalent degree has been earned). Their class work will be directed by the heads of the departments of instruction, but the greater portion of their time will be spent in research work under the direction of the Bureau staff resident at the University. The purpose of this work is to undertake the solution of definite problems confronting the mining and metallurgical industries of Idaho. For 1918-'19 the following subjects are to be investigated: (1) Differential flotation, with especial reference to the zinc-lead ores of the Coeur d'Alene; (2) availability of Western wood-oils for concentration by flotation; and (3) treatment of the complex gold-silver ores of southern Idaho. Under the ruling of the War Department, candidates 21 years of age or over who are accepted for the fellowship, will be allowed to enlist in the Engineers Reserve Corps detailed to continue their studies, and placed in a deferred classification for the period of their enrollment as graduate students.

KANSAS

Baxter Springs.—Production of the Baxter-Treese districts last week was 1375 tons of blende and 173 tons of lead, valued at \$79,485.

MICHIGAN

Houghton.—Ore production of many of the Copper Country mines fell off considerably last month, as shown by the following table, in tons:

Mine	April	March
Ahmeek	101,500	118,000
Allouez	41,200	49,000
Centennial	11,000	13,000
Copper Range group	95,000
Franklin	25,000	25,000
Hancock	12,800	16,000
La Salle	13,000	13,000
Mass	17,300	24,800
Mohawk	39,000	42,000
Osceola	87,000	105,000
Superior	10,500	9,400
Wolverine	20,000	25,000

Shortage of trammers and celebration of the conclusion of the 'wet' status of Michigan are said to be responsible for the lower tonnage.

Calumet & Hecla is to abandon the coal docks near Dollar bay on Portage lake, and will use the new and larger plant near Hubbell, on Torch lake. The fire at the old coal shed last winter resulted in a loss of \$170,000.

Part of the 10,000-ft. Nordberg hoist has been received at the Quincy mine. Foundations for this were partly laid last summer and are now being finished. This No. 2 shaft has to go 14,000 ft. before the property-line is reached. Stage hoisting has been suggested for depths below 7000 ft., but the Quincy will use the new engine for continuous hauling from 10,000 ft., if such depth can be attained. Bruno Nordberg is satisfied that the hoist will be satisfactory, in spite of the heavy rope needed and 10-ton skips.

Quincy Mining Co. has increased wages similar to Calumet & Hecla. Employees paid under \$200 per month receive 5% extra from May 1.

MISSOURI

Flat River.—On June 20 the St. Joseph Lead Co. pays 50c. per share.

Joplin.—Production of the region last week was 7773 tons of blende, 155 tons of calamine, and 1361 tons of lead. These averaged \$54, \$30, and \$82 per ton, respec-

tively. The total value was \$523,843, making \$9,089,200 for 19 weeks. The Missouri field contributed \$105,930.

According to W. W. Wampler, a mine operator of Weh City for many years, one improvement for this district would be a standardized method of making assays of drill cuttings. So many different methods are used that it is difficult to tell what to make of assays if one does not know just how the cuttings were handled.

Stark City.—Another zinc-lead field is coming to notice in Missouri, it being in prairie country south of Neosho. The Stark City Lead & Zinc Co. has a new 200-ton mill almost complete. Ore is opened at 65, 90, and 190 ft. depth, all of good grade. Other companies have good prospects.

MONTANA

Anaconda.—A new stack is being built at the Washoe Reduction Works. It will use 7,000,000 bricks made from mill slime. The height is to be 525 ft. above the 30-ft. concrete foundation. The inside diameter is 60 ft. At its base will be a battery of Cottrell electric dust precipitators.

Butte.—On account of the accident to its Black Rock shaft, whereby a skip tore out 200 ft. of timber, Butte & Superior's mill is still stopped, until No. 3 shaft can be operated.

North Butte Mining Company reports as follows for 1917: In the Butte east side mineral area, eight claims were acquired. These probably carry the eastern extension of veins that have been opened in properties contiguous to the land purchased. The general manager, Norman B. Braly, states that the cross-cut tunnel in this section was driven 1448 ft., making it 2500 ft. long. Small bunches of high-grade ore were found. A 4-compartment shaft is being sunk 700 ft. in the Sarsfield claim, to connect with the tunnel workings. At the North Butte mine, work was suspended at the Granite Mountain shaft on June 8, 1917, when fire destroyed it to a depth of 1400 ft. By January 1918 this shaft was lined with concrete. Meanwhile the Speculator shaft was used for hoisting a small quantity of ore. New work last year amounted to 12,175 ft. On the 3200, 3400, and 3600-ft. levels of Granite Mountain shaft there was driven 415, 461, and 354 ft. respectively. Results were generally satisfactory. The smelter treated 296,750 tons of ore and 23 tons of copper precipitate. This yielded 14,493,452 lb. copper, 662,846 oz. silver, and 959 oz. gold. There was treated 5770 tons of ore producing 1,222,482 lb. zinc and 8801 oz. silver. Sales included 21,087,513 lb. copper, 1,222,482 lb. zinc, 987,120 oz. silver, and 959 oz. gold. The gross income was \$4,615,217. All expenditures totaled \$3,974,090, leaving a profit of \$641,127. Four dividends absorbed \$1,075,000, equal to \$2.50 per share. Current assets at December 31, 1917, were \$2,190,149, including Liberty Bonds \$90,000, cash \$1,202,329, and metals on hand \$707,969. Current liabilities were \$184,349. The surplus of \$5,287,013 was reduced to \$3,465,270.

Contact.—A chrome deposit, assaying from 32 to 47% Cr₂O₃, has been discovered 32 miles from Big Timber by T. Rowlands and others, who have bonded it to Barker & Pardy of Great Falls for \$50,000.

NEVADA

Copperfield.—Smelter settlement of the last carload of ore shipped from the Nixon-Nevada mine shows that it averaged 33.36% copper, \$10.80 gold, and \$13.98 silver per ton. The net return from the copper alone was \$136.28 per ton. The ore was sorted into two grades of nearly equal size, and the management estimated that the first-class would carry 40% and the second-class 20%. The smelter inadvertently mixed the two grades and sampled it as one lot, but the result shows that the Nixon management was conservative.

Goldfield.—The Red Hill Florence and Florence Goldfield

companies have signed an agreement that eliminates any chance of litigation over apex rights. By the terms of the agreement the Red Hill is granted a lease for five years on all ground of the Florence company that is desired or that can be worked to advantage by the Red Hill, embracing the greater part of the Red King claim and excluding only a small area under lease and not covering the same ore-channel.

Silver Pick Consolidated Company is to sink its shaft from 1100 ft. to 1400 ft., owing to favorable indications.

Atlanta Mines Co. during its financial year ended April 1 shipped 1821 tons of \$16.23 gold-silver-copper ore. This gave a net return of only \$4.63 per ton from the smelter. The ore was not suitable for treatment by flotation at the Goldfield Consolidated mill. The shaft was sunk from 1750 to 1900 ft., where at present cross-cutting is under way. Water and other matters delayed this work, but the objective is considered to be close at hand. A raise put up 40 ft. from the bottom level has cut the foot-wall of the vein, assaying \$11 across 7 ft. A. I. D'Arcy is manager.

Goodsprings.—Mine-owners in this district are said to be storing their zinc ore in anticipation of a rise in prices. This district is described on another page of this issue.

Pioche.—Amalgamated Pioche is employing a considerable force on a lease, concentrating sulphide ore carrying 12% lead, 12% zinc, and 10 oz. silver per ton.

The Bristol-May, at Jack Rabbit, 15 miles north of Pioche, is shipping lead-silver-copper ore. This mine is near the top of a mountain. An aerial tram brings ore to the bins, above the narrow-gauge railroad.

The Black Metals Co. at Jack Rabbit has shipped one car of manganese, and is cleaning out some old workings filled with this ore. When mining for lead-silver, the manganese is screened and sold to Utah smelters for fluxing purposes. The company receives 10c. per unit for it, besides 5% lead and 6 oz. silver per ton.

The Prince Consolidated is shipping over 300 tons daily to Utah smelters.

Tonopah.—Production of the district last week was 10,261 tons of ore valued at \$180,557.

Tonopah Extension in April produced 106,427 oz. silver and 1089 oz. gold from 8529 tons, giving a profit of \$62,471. Considerable work is under way in the company's Victor mine.

Jim Butler made a profit of \$38,835 in March. In April 2542 tons was treated.

North Star has opened rich ore in the 1000-ft. intermediate level, near the Belmont boundary. A. E. Lowe is superintendent.

The Halifax Tonopah may absorb the Mizpah Extension, as the matter is under consideration.

West End Consolidated made a profit of \$354,264 during 1917. Reserves are 10,333 tons of positive, 35,905 tons of probable, and 61,111 possible ore. Work is to be started on the 800-ft. level.

Tybo.—The Louisiana Consolidated Mining Co. is operating here, 55 miles north-east of Tonopah, which is the shipping point. In the early days about \$5,000,000 of oxidized lead ore was mined. After having been shut-down for a number of years work has been resumed by the present company. Exploration has developed new lead-silver orebodies in limestone to a depth of 500 ft., and sufficient ore has been blocked out to warrant a mill. This has had a trial run, and concentrate will be shipped soon.

Virginia City.—Five north-end Comstock mines are now producing ore, an unusual occurrence. These are the Union Con., from the 2300, 2400, 2500, and 2600-ft. levels; Sierra Nevada, from 2500-ft.; Mexican, from 2300-ft. level near the Union south line; and Ophir and Consolidated Virginia, from the 2000 and 2100-ft. levels.

NEW JERSEY

Franklin.—New Jersey Zinc Co.'s net income for the first quarter of 1917 was \$3,603,796, against \$6,006,739 a year ago. Provision for Federal taxes was \$1,620,000.

OKLAHOMA

Henryetta.—The United Producers Smelting Co. is making good progress in erecting its zinc smelter and rolling-mill here. J. R. Cavanagh is one of the principals.

Picher.—Production of Oklahoma fields last week was 4619 tons of blende and 848 tons of lead, valued at \$238,438.

OREGON

Gold Hill.—Three extensive deposits of manganese have been uncovered on the Pacific & Eastern railway in the Butte Creek district, at the east end of Jackson county. Two are within two miles of a shipping point, and are on the same strike of the Lake Creek deposits a few miles south. The Tacoma, Washington, company, operating on Lake creek, is making regular shipments of concentrate and is erecting an additional unit to its plant. The company is drill prospecting its adjoining holdings, which are said to show a large tonnage of good quality ore.

The new owners of the defunct Rogue River Public Service Corporation properties, consisting of power-plants at Gold Hill and Grants Pass on Rogue river, have incorporated under the name of the Irrigation & Power Co., with headquarters at Grants Pass. The new company is composed of Indianapolis, Indiana, citizens, with Frank M. Favre at the head. Rehabilitation and operation of the properties will be resumed at once.

SOUTH DAKOTA

Lead.—On May 25 the Homestake company pays 50c. per share.

The Homestake Mining Co. has announced discontinuance of the percentage bonus, which has been added to regular wages, and the adoption of a new permanent wage-scale, also an increase to the scale to present employees for the period of the War only, as follows:

Old scale	New scale	War scale
\$2.50	\$3.00	\$3.25
2.75	3.25	3.50
3.00	3.50	3.75
3.00 Underground	3.60	3.85
3.25	3.75	4.00
3.50	4.00	4.25
3.75	4.25	4.50
4.00	4.50	4.75
4.25	4.75	5.00
4.50	5.00	5.25
4.75	5.25	5.50
5.00	5.50	5.75

Terry.—The Mogul-Ofar tunnel is in 850 ft. and will be continued 600 ft. farther. When completed it will make possible the handling of all ore from the upper workings, through chutes, at the tunnel-level. Ore will be drawn from the chutes and transported by mine-cars to the bins at the portal, from there delivered to the mill-bins by aerial tram. Erection of the tram has been completed, but until the tunnel is finished only part of the ore can be removed by this means.

Trojan.—Oberton and Arpino have leased the Juno mine and are making regular shipments to the Mogul mill.

Galena.—Charles Allen has leased the Red Cloud mine, and shipments of silver-gold ore will be made to the Trojan plant as soon as roads can be repaired.

TEXAS

Pecos.—Sulphur deposits here are to be developed. The Standard Sulphur Corporation of Detroit, Michigan, has

ordered rails and rolling-stock for a 12-mile line to its sulphur mines.

UTAH

Bingham.—Utah Copper Co. reports as follows for the first quarter of 1918:

The net profit, including dividends, etc., from other interests, totaled \$3,810,664. Dividends paid were \$4,061,225, leaving a deficit of \$250,561 for the period. In the last quarter of 1917 there was a surplus of \$3,655,069. Overburden removed amounted to 888,690 cu. yd. The mills dressed 2,498,700 tons of 1.2218% ore, a decrease of nearly 1,000,000 tons in the last quarter. Recovery was 66.80%, against 59.15%. Including ore smelted direct the output was 41,276,750 lb., compared with 51,269,465 lb. Cost per pound was 14.09 cents.

The Bingham-New Haven-Utah Consolidated apex and damage suit is to be settled out of court.

Lark.—The first two units of the Ohio Copper Co. were started last week. They have a capacity of 600 tons each. Three others will be ready by July 15. Flotation is used.

Tintic.—The Tintic Milling Co. reports for 1917 that sales of bullion realized \$542,265. Operations cost \$491,444. Depreciation and interest left a net profit of \$12,922. Current assets total \$148,640, and liabilities \$149,521. The surplus after closing the year's business was \$7716.

WASHINGTON

Keller.—Fluorspar claims of H. C. Mitchem of Spokane have been optioned to the Consolidated Mining & Smelting Co. of Canada for \$100,000.

WYOMING

A bill to appropriate \$50,000 for a mining experiment station at Sheridan has been introduced to Congress by Representative Mondell. The main object of the station would be to investigate the fuel possibilities of lignite.

CANADA

Ankox.—Granby Consolidated is erecting two new converters here. These were ordered a long time ago. Four furnaces are in blast.

Ontario

Cobalt.—The Mining Corporation of Canada is altering its mill to allow of treatment of 300 tons daily of old tailing from the bed of Cobalt lake. It has been proved that the slime from previous operations can be treated by cyanide to better advantage than by flotation. The material pumped from the lake will be first classified, the slime treated in the cyanide section of the mill, and sand, after re-grinding in tube-mills, run over concentrating tables and through flotation apparatus.

MEXICO

Sonora

Cananea.—Greene Cananea pays \$2 per share on May 27. This is payable only on the \$100 shares into which the capital stock is divided.

Mexico City.—The United States Federal Reserve Board has denied application of the A. S. & R. Co. to increase its gold shipments to Mexico. For the last several months the company has been shipping gold bars at a rate above \$500,000 monthly, in obedience to a decree of the Mexican government that mining companies shipping gold and silver out of Mexico in ore and base bullion must return 25% of the value of the silver in form of refined gold. Under a recent ruling the amount of gold return demanded for silver taken out of Mexico was increased to 50%. Permission was denied, on the ground that under the existing arrangement, Mexico is receiving all the gold that the country needs. Company officials will submit word to the Mexican government of their inability to supply the demanded gold increase, and it is hoped that authorities at Mexico City will revoke the new decree.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

T. A. Rickard is at Salt Lake City.

Walter G. Perkins is at New York.

F. L. Bosqui has returned to London.

James H. Hyde is doing research work at the University of California.

W. A. Butchart, concentrating engineer of Denver, was here this week.

Roy J. Handy is expected in San Francisco next week, from Kellogg, Idaho.

Charles F. Willis has resigned as director of the Arizona State Bureau of Mines.

R. C. Gemmell, manager for the Utah Copper Co., has been in San Francisco.

D. C. Jackling, now director of explosive-plants, was in San Francisco this week.

Morton Webber has opened a branch office at O'Rourke Estate Bdg., Butte, Montana.

R. A. F. Penrose succeeds Eugene Meyer on the directorate of the Utah Copper Company.

Norman C. Stines is reported to be a prisoner of war, taken in Finland and now in Germany.

H. C. Wilnot has returned to New York from a two months trip in New Mexico and Arizona.

G. M. Colvocoresses, manager of the Humboldt smelter, in Arizona, was in San Francisco this week.

J. B. Kendall has resigned as mine superintendent of the Goldfield Consolidated, to take effect June 1.

Albert Burch is in charge of investigations into the production of chrome for the U. S. Bureau of Mines.

H. Vincent Wallace has opened an office as consulting mining engineer in the Central Bdg., Los Angeles.

Wilbur A. Nelson has been appointed State geologist of Tennessee, filling the place of the late A. H. Perdue.

H. Sneddle, Lieutenant of the 15th Battalion, Tank Corps, British Army, has been promoted to Captain.

Edwin A. Sperry, of the department of metallurgy, in Pei-Yang University, at Tientsin, is returning to China.

C. W. Beauchamp, of Twin Bridges, Montana, is in the 28th Regiment of Engineers, Company D, at Wood Bridge, Virginia.

Herman Garlich has been appointed member of the Advisory Committee on Non-Ferrous Metals to the U. S. Tariff Commission.

Thomas J. Taplin passed through San Francisco on his way from the Spassky mine, in Siberia, to England, where he intends to enlist.

William M. Keck has been appointed consulting engineer for the Department of Petroleum and Gas of the California State Mining Bureau.

H. W. Foster has resigned as assistant manager to the El Tigre Mining Co., Sonora, Mexico, to enter the Fourth Officers Training Camp.

F. H. Probert, Professor of Mining in the University of California, has gone to Washington to do some important work for the U. S. Bureau of Mines.

F. J. Nagle, recently superintendent of the Vindicator mine at Cripple Creek, has been appointed manager for the Sunnyside Mining Co., at Silverton, Colorado.

Ernest L. Hartwell, formerly assistant-superintendent for Yak Mining, Milling & Tunnel Co., at Leadville, Colorado, succeeded Hugh C. Watson as superintendent.

W. E. Greenawalt, of Denver, has been engaged by the Nevada-Douglas Consolidated Copper Co. to act as metallurgist, while G. C. Westby of Butte is to do testing work.

Harold A. Lewis has resigned as manager to the Porco Tin Mines, Ltd., at Potosi, and is now consulting engineer to the Berenguela Tin Mines, Ltd., at Cochabamba, also in Bolivia.

H. H. Webb has been making a visit of inspection at the La Grange mine, near Weaverville, California. His nephew, T. H. Webb, the son of Louis Webb, the manager of the La Grange, was the airman that carried mail recently from New York to Washington.

Vernon F. Marsters, formerly geologist to the New York & Honduras Rosario Mining Co., San Juancito, Honduras, has opened an office as consulting engineer in the Rialto Bdg., at Kansas City; he is now in Louisiana engaged in the investigation of some oil properties in the Caddo field.

Walter W. Bradley, mining statistician of the California State Mining Bureau, received the degree of mining engineer, and E. V. Daveler, superintendent of mills, Alaska Gastineau Mining Co., at Juneau, the degree of metallurgical engineer, at the Commencement of the University of California, on May 15.

Samuel W. Cohen has resigned as general manager for the Crown Reserve Mining Co., Ltd., and Porcupine-Crown Mines, Ltd., which position he has held for ten years, to take up general consulting mining engineering practice with headquarters at Montreal. He remains with both these companies as consulting engineer.

Recent promotions at the Anaconda Copper Mining Co.'s works are as follows:

W. N. Tanner, for a number of years superintendent of the foundry department, and chief engineer of the reduction works, has been promoted to be chief mechanical engineer with headquarters at Butte. C. D. Woodward, formerly assistant chief engineer at the Great Falls reduction works, has been promoted to be chief electrical engineer, with headquarters at Butte. W. C. Capron, assistant chief engineer at the Washoe reduction works, has been promoted to be mechanical superintendent of the plant. George Tryon, formerly chief draftsman at the Washoe works, has been promoted to be assistant chief engineer of the Great Falls works. W. E. Meals, formerly superintendent of construction at the Washoe works, succeeds Mr. Tryon as chief draftsman. W. Jordon has been promoted from draftsman to superintendent of construction, succeeding W. E. Meals.

Thomas D. Kyle, well known in Colorado, died at Glenwood Springs, on April 18, after a short attack of pneumonia. He was born at Lynchburg, Virginia, on November 25, 1872. He graduated from the University of Virginia, where he secured special training in chemistry and metallurgy. Arriving at Leadville in 1892, two years later he opened an assay-office there that was maintained until his death.

The Michigan College of Mines 'Alumnus' for April gives a list of 177 M. C. M. men in the Service.

The fourth National Exposition of Chemical Industries is to be held at New York, starting on September 23. Charles F. Roth is manager.

The American Association of Petroleum Geologists was formed at Oklahoma City on February 15. The new organization is largely a change of name and widening of scope of activities of a highly successful local organization, the Southwestern Association of Petroleum Geologists, in existence for three years. Over 100 geologists from various parts of the country were present, including James F. Kemp, I. C. White of Tampico, Thomas M. O'Donnell of the Fuel Administration, R. D. Salisbury of the University of Chicago, and others. Instructive papers were read. The officers elected for the current year were president, Alexander Deussen; vice-president, I. C. White; secretary-treasurer, W. E. Wrather; and editor, Charles H. Taylor.

THE METAL MARKET

METAL PRICES

San Francisco, May 21

Aluminum-dust, large and small lots, cents per lb.	65-70
Antimony (wholesale), cents per pound	15
Copper, electrolytic, cents per pound, in carload lots	23 1/2
Copper, electrolytic, cents per pound, in small quantities	24 1/2
Lead, pig, cents per pound	7 1/2
Platinum, pure and with 10% iridium, per ounce	\$108-\$110
Quicksilver, per flask of 75 lb.	\$216
Spelter, cents per pound	9 1/2
Zinc-dust, cents per pound	17 1/2

The Government is making an inventory of the platinum metals in the country and will pay \$105 per oz. for platinum, \$175 for iridium, and \$135 for palladium.

ORE PRICES

May 21

Antimony, 45% metal, f.o.b. California, per unit	\$110
Chrome, 38% and over, California, per unit	\$135-\$150
Magnetite, crude, California, per ton (nominal price)	\$7.00-\$8.00
Manganese, 40 to 50% Mn, Hazen, Nevada, cents per unit	92-110
Manganese, 48%, New York, per unit	\$1.20
Molybdenite, per lb., 85% MoS ₂	\$1.35-\$1.50
Pyrite, domestic, New York, cents per unit of sulphur	28
Tungsten, 60% WO ₃ , California, per unit	\$24

EASTERN METAL MARKET

(By wire from New York)

May 21.—Copper is unchanged. Lead is dull, though firm. Spelter is quiet but strong. Platinum is quoted.

COPPER

On September 21, 1917, the Government fixed copper prices at 23.50c. per lb. for large lots, and 24.67c. for small lots, effective until June 1, 1918. Quotations in cents per pound are as under:

Date	Average week ending
May 15.....	23.50
" 17.....	23.50
" 18.....	23.50
" 19 Sunday.....	23.50
" 20.....	23.50
" 21.....	23.50

Monthly averages

Date	1916	1917	1918
Jan.....	24.30	29.53	23.50
Feb.....	26.02	34.57	23.50
Mch.....	26.65	36.00	23.50
Apr.....	28.02	33.16	23.50
May.....	29.02	31.89	23.50
June.....	27.47	32.57	23.50

Copper production of some of the larger mines in April are as under:

Name	Pounds	Name	Pounds
Braden.....	4,722,000	Granby.....	3,048,012
Calumet.....	3,974,000	Ingersoll.....	5,550,000
Calumet & Hecla and subsidiaries (C. & H.).....	11,734,820	Kennecott.....	5,794,000
Chile.....	7,770,000	Mohawk.....	944,302
Davis-Daly.....	669,366	New Cornish.....	3,728,000
		Volcanine.....	381,989

SILVER

Below are given official (not Government) quotations, in cents per ounce of silver 999 fine. In order to make prompt settlements with smelters and buyers, producers allow a discount from the Government price of \$1, hence the lower price. The Government has not fixed the general market price at \$1, but will pay this price for all silver purchased by it. The equivalent of dollar silver (1000 fine) in British currency is 10.65 pence per ounce (925 fine), calculated at the current rate of exchange.

At the end of last year the melting of silver dollars at the New York Assay Office was stopped, owing to the lack of silver certificates. It is now proposed to ship the coins without melting, by mutilating them as prescribed in the new Act.

Samuel Montagu & Co. of London, writing on April 25, say that the price has now reached a point at which silver costing \$1 per fine ounce on the other side of the Atlantic can be supplied to this (London) market at a reasonable profit (insurance, freight, etc. included). Unless something unexpected happens, future movements of the price are likely to be on a very limited scale. Important legislation passed by the U. S. government, which, while demonstrating the cordial co-operation in finance

between it and Great Britain, relieves the strain of providing silver for Indian coinage. The bill grants power to melt 350,000,000 silver dollars (about 371,000,000 fine ounces), and to dispose of the bullion, to be replaced by subsequent purchases. As information has been received from India that the Indian government has secured 150,000,000 oz. from the U. S. government, a further 121,000,000 oz. is available for such purposes as America may desire. The amount of 150,000,000 oz. is sufficient to provide 1463 lacs (1 lac = \$2,000) of rupees, a sum that should be adequate to meet currency demands for some considerable time. It was announced in Parliament on April 21 that 198,000,000 fine oz. had been purchased for coinage between February 1915 and March 31, 1918, at an average price \$9.0341. The holding of silver by the Indian Treasury on January 31, 1915, was 3030 lacs, and on March 31, 1918, 1079 lacs—a reduction of 1951 lacs. As 198,000,000 oz. can be minted into 5700 lacs of rupees, the net absorption in the period mentioned was 2711 lacs. Therefore even at the high rate of absorption indicated, 150,000,000 oz. would suffice to maintain the silver holding at the same level for about 2 1/2 months.

The stock in Shanghai on April 20 consisted of 32,000,000 oz. in specie and 14,700,000 dollars, compared with about 32,250,000 oz. and 14,700,000 dollars on April 13.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound. In February 1918 the Government fixed prices for grade A spelter at 12c. per lb. for itself and the open market. This grade constitutes only a small proportion of the total output. Lower grades can make their own prices as usual. Sheet-zinc is fixed at 15c. per pound.

Second-grade ore at Joplin is \$2.50 per ton higher at \$42.50. The market shows signs of betterment.

Zinc production of Butte & Superior in April was 14,100,000 lb., also 250,000 oz. of silver.

LEAD

Lead is quoted in cents per pound, New York delivery. Government metal receives 7c. per lb. until August 6.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. The Government is taking part of the United States quicksilver output, paying therefor \$105 per flask. Outside of this business the competitive market can make any price as usual. Prices, in dollars per flask of 75 pounds:

There have been sales of Chinese tin in New York at 90¢, while Straits is nominal at \$1.05 per pound.

Eastern Metal Market

New York, May 15.

Two of the markets exhibit a stronger tone and have developed higher prices, but all of them are inactive as compared with a normal market.

Copper is in strong demand and rather scarce for May delivery.

Tin is at a standstill with few transactions recorded or possible. Prices are no higher than a week ago.

Lead is not so plentiful and is firmer and higher.

Zinc, while not particularly active, is higher and displays a firm undertone.

Antimony has declined.

Aluminum is under Government control.

In the steel world the capacity in all lines is ample, but it is the spectre of a short supply of fuel that lies behind the predictions of long continued monopoly of the steel output by the Government. Ingot production in April was at the yearly rate of 43,000,000 tons, which would mean a considerable surplus above war needs, direct or indirect. Interesting news is the selection of Neville Island, near Pittsburgh, as the site for the great gun and projectile plant to be built by the Government and the Steel Corporation. It means the early letting of large orders for structural steel and equipment. Guns will not be turned out for 18 months, but the plant will cost \$60,000,000 to \$70,000,000. Ship-plates and shell-steel programs have been expanded in the past week. Pig-iron is under close Government control as to sale and distribution, and the inability of cast-iron pipe makers to get enough iron to keep going is a serious question.

COPPER

There is little news; the entire trade is eagerly and somewhat anxiously awaiting the outcome of the meeting at Washington on May 22, when the final discussion will take place as to any change in the 23.50c. price of copper, effective until June 1. It is estimated on good authority that if the average small producers are forced to shut-down through the paring of profits to the vanishing point by reason of rising costs, there will be a loss in the output of not less than 100,000,000 lb. per year. This is not a negligible quantity as consumption goes now-a-days. Demand for May delivery, from British and French consumers particularly, and from others as well, is so large that there is doubt whether the refiners can meet it. Demand from all quarters is good but there is not much disposition to book orders far ahead until the supply and the demand are accurately analyzed. The output of two or three large companies for the first quarter is not as large as that of the last quarter in 1917. Many confidently predict an advance over the present Government price of perhaps $\frac{1}{2}$ to $\frac{1}{4}$ c. per lb., making it 24.25 to 25c. per lb. after June 1. At least no reduction is probable, in view of all the conditions.

TIN

For the first week in a long time there have been no advances in prices; they have gone to what has seemed the high mark; they may go higher yet, but they have stopped temporarily. The week has been quiet, and it is expected that the inactivity will continue. Small quantities of tin for future shipment from the Far East have been sold at 97 to 98c., principally May, June, and July delivery. These offerings, while few, have been quickly snapped up, and more could have been disposed of had they been offered. The metal is still scarce for any position, and the situation is not reassuring. For spot delivery as high as \$1 or \$1.05

is the nominal quotation, and this would readily be paid for any offerings. An unconfirmed rumor states that \$1.25 was offered for a 10-ton lot of Straits tin for prompt delivery, and this is highly probable. Arrivals to May 14 inclusive have been 645 tons, with 5000 tons estimated to be afloat. The London market is easier, with spot Straits quoted at £370 per ton, a decline of £11 in the last week.

LEAD

The feature of the lead market is the fact that offerings of prompt lead are scarce. With quotations up to 6.90c., New York, or 6.70c., St. Louis, yesterday for early delivery the market is considerably stronger than a week ago. The cause is that the lead that certain sellers were pressing on the market in the last few weeks has been absorbed, resulting in more buyers than sellers. The stronger position has been developing gradually, and it is a question whether it is temporary or not. Opinion is divided as to this. The present outside quotations are again close to that of the American Smelting & Refining Co. of 7c., New York, which has remained unchanged for some time.

ZINC

The better tone noted in last week's letter has continued to develop until now the market is quite a little stronger. For early delivery of prime Western 7.25c., New York, or 7c., St. Louis, is asked and obtained, with as high as 7.37 $\frac{1}{2}$ c., St. Louis, wanted by some sellers. The quotation for June is 7.37 $\frac{1}{2}$ c., St. Louis. While there are inquiries for third quarter, there is little disposition to sell as far ahead. The Government has been a large buyer of grade A and is now inquiring for more, as well as for 1000 tons of grade C. These demands have contributed to the stronger position. Another cause of the higher levels is the fact that considerable metal was taken out of the market at the recent low levels and sellers are not now eager to sell at present levels and on an apparently rising market.

ANTIMONY

Because some sellers offered holdings at a considerable concession from prevailing prices the market has declined and is quotable at 12.50 to 12.75c., New York, duty paid, for Chinese and Japanese grades.

ALUMINUM

Government prices continue to control the sale of No. 1 virgin metal, 98 to 99% pure. These range from 32 to 32.20c. per lb. in lots of 50 tons down to one ton.

ORES

Antimony: The market is entirely inactive, with prices nominal at unchanged levels.

Ferro-manganese: It has been virtually decided to permit the importation of about 10,000 tons of British ferro-manganese inside of the next two months before completely shutting off the imports as planned for May 13. This is due to the fact that ore imports in April will be unusually low.

Manganese: It is interesting to note that of the 19,300 tons of March imports of high-grade ore, about 10,000 tons came from Cuba and only 6000 tons from Brazil.

Molybdenum: Sales have been made at \$1.25 to \$1.50 per lb. of MoS₃ in 90% material, depending on the quality. These prices are being shaded on large quantities.

Tungsten: The week has been quiet. What little business was done is reported to have gone at the usual prices of \$24 to \$24.50 per unit in 60% concentrates. Ferro-tungsten is unchanged at \$2.25 to \$2.35 per lb. of contained tungsten.

Company Reports

CALUMET & HECLA MINING CO., AND SUBSIDIARIES

Properties: situated in the Copper Country of Michigan.

Operating Officials: (C. & H.) general manager, James MacNaughton; assistant superintendent, W. M. Gibson; chief mining captain, John Knox; mill superintendent, Henry Fisher; metallurgist, C. H. Benedict; and smelter superintendent, H. D. Conant. (Ahmeek) superintendent, S. R. Smith; mining captain, Thomas Rapson; and mill superintendent, A. L. Burgan. (Allouez) superintendent, F. W. Ridley; and mining captain, J. J. Gibbens. (Centennial) mining captain, J. H. Chynoweth. (Isle Royale) mine superintendent, J. E. Richards; chief mining captain, Edward Colenso; mill superintendent, A. G. Andrews. (La Salle) superintendent, O. Hallingby; mining captains, William Skewes and Josiah Bartell. (Osceola) superintendent, F. H. Haller; mining captains, James Rowe, Joseph Discombe, and Frank Lands; and mill superintendent, A. L. Burgan. (Superior) superintendent, Ocha Potter. (White Pine) superintendent, T. H. Wilcox.

Financial Statements: the year 1917 shows the following results:

Company	Copper sales	Operating profit	Balance Jan. 1, 1917	Balance Dec. 31, 1917
Calumet & Hecla	\$16,900,576	\$9,154,450	\$10,758,602	\$10,626,485
Ahmeek	5,180,901	3,362,590	2,233,364	1,505,444
Allouez	2,051,297	1,035,630	1,545,814	1,157,703
Centennial	454,123	139,697	448,368	436,107
Isle Royale	2,750,637	1,139,745	923,552	890,740
La Salle	440,151	128,592	173,492	308,842
Osceola	3,453,758	1,736,915	2,677,549	2,410,190
Superior	469,721	199,859	134,313	489,293
White Pine	800,523	404,673	613,908	509,733

Calumet & Hecla's net miscellaneous income—dividends from other companies, silver, etc., was \$3,977,943.

Taxes were as under:

	Income tax, 1917	Excess profits tax, 1917
Calumet & Hecla	\$409,189	\$570,286
Ahmeek	112,999	809,761
Allouez	40,770	204,722
Centennial	4,384
Isle Royale	53,242	133,377
La Salle	7,300
Osceola	55,469	496,935
Superior	6,172	4,462
White Pine	16,961	17,307

Dividends: those paid in 1917 and to date are as under:

Company	1917	To end of 1917
Calumet & Hecla	\$8,500,000	\$145,250,000
Ahmeek	2,800,000	10,050,000
Allouez	1,050,000	2,300,000
Centennial	90,000	150,000
Isle Royale	600,000
Osceola	1,346,100	16,002,575
Superior	100,000
White Pine (pfd. shares)	29,063

Development: in the conglomerate section of the C. & H. new drifts were 2942 ft. long. Shaft-pillars and arches being removed employed 89 drills, yielding 505,682 tons. In the Osceola section there was 338 ft. of shaft-sinking done, also 16,352 ft. of new drifts. In the Ahmeek mine sinking amounted to 964 ft., also 16,085 ft. of other work. On No. 18 level of No. 2 shaft a storage-battery locomotive was installed. Others are to be used on No. 17, 19, and 20 levels of this shaft; No. 18 of No. 3, and No. 14, 15, 16, and 17 of No. 4. New openings in the Allouez amounted to 2838 ft. Ore exposed is of average quality. Five electric locomotives are working at No. 2 shaft. Including 244 ft. of sinking, Centennial development covered 1653 ft., mainly on No. 38 level north. Isle Royale did 996 ft. of sinking, also 19,271 ft. of other work from 7 shafts. La Salle sank No. 2 shaft 163 ft. to 2242 ft. depth. Other work totaled 2145 ft. Exploration by the Osceola company in La Salle ground was stopped in November owing to difficulties of operation. In the Osceola mine, development amounted to

6445 ft. in the three branches. Above No. 46 level and near the extreme south and west boundaries of the Osceola branch was the most productive ground. In the Superior there was 198 ft. of sinking and 2502 ft. of driving done. Reserves are estimated as 150,000 tons. White Pine sank No. 2 shaft 755 ft. to a depth of 1078 ft. Gray sandstone was cut at 800 and 900 ft., a better lode being disclosed on the latter level than on 800 ft. From No. 4 shaft 1000 ft. of drilling was done on No. 4 level, showing No. 2 lode to be fair and No. 3 poor.

Production:

Mine	Ore, tons	Copper, lb. per ton	Yield, lb.	Cost, per ton	Cost, per lb., cents	Received, per lb., cents
C. & H.	3,159,570	21.65	68,419,826*	\$2.52	13.01	28.39
Ahmeek	1,271,275	25.00	27,919,812	1.74	9.42	26.84
Allouez	566,674	15.69	8,892,915	1.87	13.84	27.95
Centennial	148,332	13.50	2,002,857	2.33	18.67	26.06
Isle Royale	922,160	14.60	13,480,921	2.02	15.74	26.87
La Salle	185,014	10.38	1,919,775	1.87	20.14	28.45
Osceola	1,237,805	13.00	16,084,958	1.63	13.86	27.89
Superior	129,587	16.99	2,201,672	2.50	16.88	29.39
White Pine	212,889	19.11	4,067,529	2.37	14.99	28.30

*From mine only. In addition was 9,075,457 lb. recovered by the reclamation plant which pumped 730,543 tons of sand from Torch lake, classified it, re-ground the coarse material, and leached all by ammonia. This sand carried 17.06 lb. per ton, of which 12.42 lb. was saved at a cost of 5.94c. per lb., exclusive of smelting and selling.

Costs: on a per ton basis these rose 49c. at the C. & H., 28c. at Ahmeek, 19c. at Allouez, 41c. at Centennial, 49c. at Isle Royale, 3c. at La Salle, 27c. at Osceola, 43c. at Superior, and 29c. at White Pine.

HECLA MINING CO.

Property: mines at Burke and mill at Gem, Idaho.

Operating Official: James F. McCarthy, general manager.

Financial Statement: income from metals, etc., in 1917 totaled \$3,671,818. Operating charges were \$1,507,868, leaving \$2,163,950 net.

Dividends: these amounted to \$1,600,000, making \$6,905,000 to date.

Development: this work covered 12,386 ft., including 210 ft. of sinking, and 3473 ft. in the Ore-Or-No-Go mine. The shaft is being sunk to 2000-ft. level. Ore-reserves are estimated as 1,326,399 tons.

Production: the last four years compare as follows:

	1917	1916	1915	1914
Ore mined, tons.....	374,213	250,559	148,675	123,875
Concentrate shipped, tons.....	30,334
Crude ore shipped, tons.....	14,474
Zinc slime shipped, tons.....	709
Total.....	45,517	40,892	26,214	20,052
Metal in ore:				
Lead, per cent.....	48.75	49.25	47.55	47.25
Silver, ounces.....	30.00	29.30	26.40	25.40
Zinc, per cent.....	7.65
Lead produced, pounds.....	44,363,559	40,217,573	24,917,867	18,957,823
Silver produced, ounces.....	1,366,960	1,195,841	692,444	509,200
Zinc produced, pounds.....	507,888

Costs: mining cost \$2.5333; development, 35.4c.; sorting, 17.7c.; milling, etc., 68.6c.; and general, 42.9c., a total of \$4.029 per ton.

WAIHI-PAEROA GOLD EXTRACTION CO.

Property: tailing claims on the Ohinemuri river, 20 miles below Waihi, New Zealand. Old tailing from mills in the mining districts is dredged from the river, ground in 22 tube-mills, and cyanided. One section has been dredged 30 times, being re-filled by floods.

Financial Statement: out of the profit of £10,529 (\$49,000) made in 1917, £6250 (\$29,800) was paid as a dividend.

Production: the plant treated 147,700 tons of slime (ground sand), yielding gold and silver valued at £52,479 (\$254,000). In 1916 the output was \$43,000 less. So far there has been treated 845,000 tons.

Book Reviews

Handbook of Engineering Mathematics. By Walter E. Wynne and William S. Spraragen. Pp. 220, ill., index. D. Van Nostrand Co., New York, 1917. For sale by 'Mining and Scientific Press.' Price, \$2.

This is an engineer's handy volume, giving the elements of algebra, geometry, plane and spherical trigonometry, plane and solid analytic geometry, calculus, hyperbolic functions, differential equations, theoretical mechanics, mechanics of materials, hydraulics, flow of fluids, electricity, measurement, physical and chemical constants, together with tables of circles, powers, roots, reciprocals, common and natural logarithms, trigonometric functions, and hyperbolic sines and cosines. As an example of the treatment, we abstract the following:

"Torque

The torque of a dynamo in foot-pounds equals

$$T = KI\phi$$

where ϕ = total field flux in magnetic lines, cutting armature conductors,

I = armature in amperes.

K = constant terms for any given dynamo. Its value is

$$K = \frac{2.218}{10^9} tP, \quad t \text{ being the number of armature turns in series, and } P \text{ the total number of poles.}$$

The torque of a motor in terms of the horse-power is

$$T = \frac{33,000 \text{ H.P.}}{2\pi n}$$

or solving for horse-power,

$$\text{H.P.} = \frac{2\pi Tn}{33,000} = \frac{2\pi RFn}{33,000}$$

n = number of revolutions per minute,

T = torque in foot-pounds,

R = radius of pulley in feet,

F = turning force in pounds."

Everyman's Chemistry: The Chemist's Point of View and his Recent Work Told for the Layman. By Ellwood Hendrick. Pp. 374, index, bibliography. Harper & Brothers, New York, 1917. For sale by 'Mining and Scientific Press.' Price, \$2.

The popular scientific treatises by Mr. Hendrick are well known. They have been justly accepted by the public with the enthusiasm that the public always displays toward scientific subjects when presented clearly and brilliantly, couched in simple terms, and emanating from a person that can speak with authority. The book is thoroughly scientific in the sense that the development of the subject is along scientific lines. A man knowing no more chemistry than is contained in this book would have a very broad outlook upon the constitution of the world in which he lives, and he would better appreciate the complexities of modern industrial life and the needs of the Nation in stimulating and maintaining production of the many important essentials in War as it is conducted today. This is in no sense a war book, but its bearing upon the struggle should be very great, because it will help men who are not familiar with chemistry to obtain a grasp of the chemical bases of modern industrial life. The volume discusses air and water, the halogens, sulphur and its compounds, phosphorus, arsenic, antimony, bismuth, the alkali metals, sand and clay, lime and magnesia, iron and steel, and many metals both common and rare. With special facility the author undertakes to elucidate the principles of organic chemistry, starting with the carbon molecule and the simple hydrocarbon CH_4 , from which he develops correctly the modifications that lead to the vastly complicated products of which there is no end. He promptly, however, comes to the

practical application of organic chemistry in the discussion of olefins and acids, alcohol and some of its derivatives, fats, oils, sugar, starch, and gums. Cellulose and nitrogen compounds, the aromatic compounds, and the coal-tar derivatives constitute the remainder of the book, with the exception of some valuable appendices. In this discussion the author reveals the chemistry of the common things of life, such as industrial alcohol, soaps and their uses, cane and beet sugar, gums, varnishes, paints, bread-making, explosives, artificial silk, paper, benzol, picric acid and aromatics, and dyes. Any man with an ordinary high-school education will be able to read the book, and it is so delightfully written that it is a pleasure to read it. We would suggest that the technical men who happen to be identified with operations involving organic chemistry would find it a most useful and delightful means for reviewing the subject in the light of modern manufacture.

Mining Decisions

Mining Corporations—Posting Balance-Sheets

California Civil Code section 588, requiring all California mining corporations whose stocks are listed for sale on public exchanges to keep posted in their offices balance-sheets, duly verified and showing their correct financial condition, has been held to apply to California corporations organized for the purpose of conducting mining in another State.

Overton v. Noyes (California), 170 Pacific, 1110. February 5, 1918.

Mining Option—Notice of Non-Exercise

Where under a lease and option for the purchase of mineral lands it was provided that unless the lessee gave notice on or before a certain date that he would not exercise the option, he should be held to have exercised it. A letter written before that date announcing that he intends to give notice of non-purchase does not constitute notice, nor does a notice written a week after the expiration of the date allow the lessee anything. He was held bound to pay the purchase-price in a suit for specific performance.

Mackey Wall Plaster Co. v. United States Gypsum Co. (Montana), 244 Federal, 275.

Mining Partnership—What Constitutes

Two miners bonded their claim to a third, who interested two other persons in the development of the claim under an agreement to convey them each a third if the option should be taken up, and to personally take charge of the management, control and operation of the mine, they to take care of the payments on the bond and expenses of operation, etc. The working party to the agreement continued operations for a number of years during which the other two advanced the payments under the bond and enabled him to acquire title in his own name. Subsequently he was compelled to mortgage the claim for expenses and advanced considerable sums himself for development and assessment work, on all of which indebtedness he was refused reimbursement by the other two. Held, that a complaint setting up the above facts, seeking to hold the other two for an accounting as partners in the transaction and to have the working partner declared a trustee for them as to a two-thirds interest in the mine, stated a cause of action, and the demurrer thereto was improperly sustained. It is not essential that all mining partners should actually engage in physical work on the claim. It is sufficient to constitute a mining partnership under Section 2511, Civil Code, if one or more works and the rest merely furnish the money.

Harper v. Sloan (California), 169 Pacific, 1043.

EDITORIAL

RUMOR is current at Washington that one of the early bureaucratic changes likely to be made by the President under the authority of the Overman Act for re-distribution of departmental functions will affect the status of the Geological Survey and the Bureau of Mines. It is thought that consolidation of these bureaus under a single executive head may be effected, the activities of the staff then being limited to war work exclusively.

COMPULSORY subscription to war-loans has been ordered by the government of New Zealand. This is the first instance of the kind among the Allies during the pending conflict. Only those persons whose taxable income exceeds £700 are affected, and they are required to subscribe an amount equal to three times the total land and income tax, exclusive of excess profits contributions, which they are obliged to pay under the Finance Act of 1916.

CHROME ore occasionally enters the port of San Francisco from Australia and the South Seas. In April the arrivals amounted to 1000 tons. During the month of May 1500 tons was received, and as much more is due. It comes in the form of ballast with cargoes of wool, chiefly from Melbourne. The quantity available in this manner, however, is so small as to exert no effect upon the market price, nor does it lessen the need of strenuous efforts to produce from domestic mines.

WITHIN the last three weeks \$30,000,000 worth of silver certificates has been withdrawn from circulation, as the coin which secured them was melted into bullion under the new Silver Act. They are to be replaced by Federal Reserve banknotes of \$1 and \$2 denominations, constituting the first war-currency that has been issued up to the present time. The face of the \$1 note will carry the portrait of George Washington and the \$2 note will be distinguished by the portrait of Thomas Jefferson.

A principle that may serve as a useful model in connection with future regulations concerning restricted imports was applied by the War Trade Board on May 8 with regard to rubber. The amount that may be brought to the United States is limited to 100,000 tons per annum, but profiteering is prevented by fixing the price of the crude article from the time of importation until it passes into the hands of the manufacturer. It may be remarked

that rubber is one of the few materials that has not advanced in value during the War. The price established by the Government is practically that which was ruling in the market, being only 68 cents per pound for the highest grade. This is about one-third the market value fifteen years ago.

SOME time ago the Navy Department issued a call for the loan of field-glasses to aid our sailors in detecting submarines. The Department now confronts a shortage of sextants, chronometers, and aneroids, and a similar appeal is made to the people for a fresh display of interest in the work of war by offering instruments of this kind to the Government. They will be tagged for identification so that, if they come safely through the conflict, they will be returned to their owners. Contributions may be sent directly to the Navy Department at Washington, or to the branch Hydrographic Office in the Merchants Exchange building, San Francisco.

MEXICO'S attempt to dip into our gold reserve, by requiring exporters of silver to re-import half its value in the form of gold bullion, has come to naught. When only 25% of the value of the silver was made returnable in gold the American Smelting & Refining Company needed about \$500,000 worth monthly for the purpose. Carranza saw his chance to get a round million. He tried to bluff us by an implied threat to destroy the smelting company's business, but the Federal Reserve Board refused to supply the gold, and the obnoxious order was recalled. To pay gold for silver is contrary to time-honored custom in this country, and we strain a point in letting Mexico have even 25% of the value of the imported silver in the form of the yellow metal.

ON May 21 the President signed the so-called Sedition Act, which is primarily directed toward the suppression of hostile criticism of the Government by enemy aliens and sympathizers with Germany. It is a measure adequate for the purpose and is sweeping in its restrictions upon free speech, in so far as strictures upon the authorities may indicate a purpose to hamper the conduct of the War. There are two kinds of criticism, destructive and constructive. The first is exceedingly easy and is usually invidious, but constructive criticism requires understanding and is helpful. Not only does this remain open to all men possessed of sufficient capability to give it, but it will be welcome. Whoever can contribute in

this useful manner to the welfare of the country is one that also will know how to do it without descending to aspersions upon those who are struggling to save our national heritage from the ruthless Hun.

ATTENTION was called recently to the interesting fact that Argentina established a credit of \$40,000,000 with the Federal Reserve Bank in the United States, to be accumulated by deposits to this account by importers as a means of covering the balances due on goods brought from that country. This was equivalent to an advance of gold, since otherwise it would have been necessary to export an equal amount. Against this credit the Argentine government has issued paper currency, thereby utilizing the trade balance as a means for improving financial conditions at home. The plan has proved so satisfactory that arrangements have been made for increasing the credit to \$80,000,000. It also has encouraged Peru to avail herself of the same advantages in the promotion of more active trade with the United States. The amount of the first Peruvian credit will be \$20,000,000. Such relations tend to cement the interests of the countries concerned, and to cultivate friendly feeling.

LAST week we published a vigorous opinion on the Government's plans for accelerating the output of the rarer minerals written by the kind of man from whom the officials at Washington are eager to hear. We refer to the article in our discussion columns on the treatment of tungsten ores by Mr. J. H. Ratcliffe. He is not only a producer, but he represents the hard-headed hard-fisted type that works in his own mine and mill with his own hands. This is the class of man the Government chiefly must rely upon for the augmented supply of manganese, chrome, tungsten, and other materials specified in the War Minerals Bill. His statement that the miners merely require a fair price fixed definitely for a reasonable period, so that they may plunge into the work without danger of becoming financially swamped, sustains the argument we have presented from time to time, and shows that Mr. Pope Yeatman was a well-informed counsellor when he urged the Senate Committee on Mines to re-instate the price-fixing authority in the bill, which the House unwisely had excised.

SOCIAL aspects of industry increasingly engage the attention of mining engineers. The War and its impact upon society have brought into prominence the human side of the fundamental relations between capital and labor. We take pleasure therefore in printing an address delivered recently at Boston by Mr. J. Parke Channing, a member of the profession distinguished for his enlightened interest in this vital subject. Mr. Channing speaks not only as an experienced consultant and engineer of mines but as an employer of labor on a big scale. It is a keen pleasure to note the emphasis he places on the need for assimilating our foreign labor elements, for Americanizing the alien masses that perform so large a part of the spade-work of the mining in-

dustry. Undoubtedly this melting-pot of ours will fail in its social and political metallurgy unless its operations are supervised and directed in a consciously intelligent way by those sufficiently far-seeing to appreciate its great import to the future of this nation—a nation composed of ethnic fragments broken from Europe. 'Human engineering, is a subject that should appeal to earnest educated men, of the type represented by graduates from our mining colleges, especially those that by skill and good fortune have advanced to positions of influence in the mining world. Among the many ways of furthering this splendid purpose of Americanization is to co-operate with the Y. M. C. A., as Mr. Channing has done at Miami, by establishing quarters where the foreigner is given opportunities to learn English, to obtain technical instruction, and to engage in healthy athletics, all of these tending to promote an understanding of America and the American ideal, that ideal being to give every man a chance.

Re-Sale Prices

One of the developments of modern intensive commercialism has been the obligation placed upon buyers of manufactured articles to re-sell at prices fixed by the original producer. It has been one of the cardinal points in the system of trade proprieties recognized as a sort of ethical code among business men. This dictum of the manufacturer follows a trade-mark as well as a patent-brand from the shop at Pittsburgh, Chicago, or San Francisco to the miner at Grass Valley, Cottonwood Canyon, or Miami. It makes the drill-steel, the shovel, the mine-car, cost more than it might, because under-selling has been prevented. It is not surprising that these practices should soon have commanded the attention of the courts and of the Federal Trade Commission, since they involve the principle of restraint of trade. Suppression of such restraint has become, in the opinion of trade organizations, which express the views of aggressive business, an irritating fad, while the people have seen in the growth of the practice a tendency to evade in subtle ways the fundamental ideals of natural trade, so jealously safeguarded in the Constitution. As a problem in political science this is one of the most vital that has come before the country in these later years. Recent decisions have now declared the practice of fixing prices for re-sale to be illegal. The decisions are broad and unequivocal. Whatever one may think regarding the matter, or however defensible may seem his contrary argument, no doubt remains as to the case-law that now has added its sanction to the statutes. Open competition henceforth is required; the trinity of 'trade-mark, quality, and price' must hereafter give place to the duality of 'brand and quality' alone. This should benefit the 'brand of quality' after all, for, if the retail price can be clipped, the 'just as good' will be more surely passed by in favor of the article with the trade-mark emblematic of superior excellence. This but accentuates the element of effectiveness in the well-known economic principle of comparative advantage.

The wide inclusiveness of the new ruling appears from the decision of the Supreme Court last March on the injunction issued by the lower courts restraining the Boston Store of Chicago from selling talking-machine records at less than the authorized price in violation of a contract with the American Graphophone Company. The Court affirmed its right of jurisdiction under the patent laws, and then answered with a flat negative the question "Can a patentee, in connection with the act of delivering his patented article to another for a gross consideration then received, lawfully reserve by contract a part of his monopoly right to sell?" In line with this, but giving it a far broader scope, is the formal finding of the Federal Trade Commission in the case of *Chester Kent & Company*, proprietary medicine manufacturers of Boston. Reference is made by the Commission to the need of an interpretation of the law to settle the controversy in progress throughout the country over the right of manufacturers, wholesalers, and others, to fix re-sale prices for articles after passing from their hands in the general course of commerce. The case was clearly taken to have the significance of a test, and the order issued held the following: the seller is prohibited from indicating to dealers the prices for which the commodities sold, whether patented or not, may be re-sold; the seller is forbidden to secure from dealers any agreement to adhere to fixed prices; moreover it is unlawful to refuse to sell to dealers who fail to adhere to such re-sale prices, or to refuse to sell to such parties upon the same terms as to other dealers who may elect to observe the restrictions; and finally it is forbidden to furnish any advantage to dealers who are willing to observe the wishes of the seller as to an official fixed price. It is suggested by Justice Brandeis that the only remedy may be found in Congressional action, but it will be extremely difficult to cover the case by an act that will stand the constitutional test. The law of the land now is: One price to all, no left-handed favoritism allowed, and a thing once sold becomes the absolute property of the buyer, to do with as he likes.

Flotation Physics

BY HENRY F. TAYLOR

We publish a suggestive article on a phase of flotation by Mr. W. H. Coghill, to whom we have been indebted for several useful contributions to the science of the subject. He addressed the local section of the Institute in San Francisco early in April and on that occasion discussed the contact-angle of water on glass, with sundry of its applications to flotation. A glass boat, 60 by 140 millimetres, floating on water and carrying small weights, such as two corks and a pencil, served as the exhibit on which he lectured. Along the edge of this glass plate a groove had been cut to a re-entrant angle of 60 degrees, which is the contact-angle of water on glass. A similar disc of window-glass 77 millimetres in diameter floated with a load of 10 grammes of sand. The glass lay in a depression three millimetres deep and displaced a weight of water equal to 25 grammes, this being

the head or pressure that stabilized the floating. The phenomenon is that of surface-tension, which varies with different liquids, as we all know. Given the surface-tension and the specific gravity of a liquid, its contact-angle can be ascertained by a curve established by Mr. Carl O. Anderson, who has co-operated with Mr. Coghill in his research at the Seattle station of the U. S. Bureau of Mines. A drop of water has a maximum height of 5.4 mm. More water does not increase the height of the drop, but advances the edge; and when the water reaches the edge of a glass plate, for example, its height increases before it breaks. The maximum height of 5.4 mm. is reached when the edge of the plate has an angle equal to that of the advancing water, namely, 60 degrees. From this it is deduced that the most floatable substance, on ordinary water, is one having a re-entrant angle of 60°; also that the larger the angle of contact, the better it floats. It is possible that the separation made in the flotation-cell between sundry metallic minerals is dependent upon their systems of crystallization and the character of their fracture. Mr. Coghill also exhibited charts showing the action of various oils, which are divisible into those that reduce the surface-tension to less than 62 dynes when present in the proportion of 0.1%, and those that reduce the surface-tension to less than 65 dynes under the same conditions. The maximum effect was to reduce the surface-tension to less than 45 dynes. Here he explained the drop-weight method for testing oils, as outlined in the article we publish this week. When insoluble oils are used their effect must be due to emulsification. The accumulation of oil at the surface of a flotation-cell, after it has been in operation for some time, is proof of this deduction. At this meeting, mention was made of the experiment by Mr. A. F. Taggart to prove the greater floatability of uncoiled aluminum as compared with the oiled metal. We referred to this at the time when it was published and expressed regret that the publication of it in a bulletin of the Institute did not provoke discussion. The experiment was made with a heavy oil, namely, oleic acid, and that may explain the failure on the part of others to duplicate the results obtained by Mr. Taggart. Moreover, there is this to be said: aluminum is non-corrosive largely because it is promptly covered by a thin film of oxide, which gives it a surface of non-metallic lustre. That may be why it behaved so queerly in Mr. Taggart's experiment. Assayers will recall the fact that milligramme weights, which are made of aluminum, are allowed to season for a year in order to stabilize them; likewise the lead used for sheathing vats in acid-works becomes coated with sulphate, whereby further solvent action is checked. In any event, it is incumbent upon specialists to investigate the matter, which otherwise is so subversive of even the most elementary notions on the subject. Writers on flotation may have placed too much stress on surface-tension in 1915 and 1916, and we do believe now that viscosity plays an important part, but surface-tension, particularly in its variability, remains a fundamental factor. Floatability may be regarded as depending on the area of surface around the edges of which the three

phases—air, liquid, and solid—meet. Flaky minerals float because they present a large area of face in relation to their mass. The reduction of the angle of contact at the interface is another point. Time is an element of viscosity, and non-frothing oils increase such viscosity. The mineral particles subjected to flotation in the mill are mostly so much larger than colloidal particles that we cannot fall back on this interpretation for the principal phenomena. In the end flotation is the result of the forces of cohesion and adhesion pulling against gravity. The modifying agents are many and new ones are being discovered every day. There lies the hope of further development in mill-work. Meanwhile we hazard a definition of the flotation process in terms of our present knowledge.

Flotation is a process in which a multitude of bubbles, developed in a pulp of ore, is utilized as a means for separating valuable minerals from the valueless gangue. This separation is based on the fact that sundry minerals (especially sulphides) exhibit a preference for air-bubbles when these are made in a liquid modified for the purpose by the addition of a substance that produces a variable surface-tension. The bubbles result from the dispersion of air in the pulp, whether entrained by agitation or blown through the porous bottom of the vessel in which the operation is conducted. These bubbles rise, and the variable surface-tension produced by the modifying agent added to the water hinders the coalescence of the bubbles while they are rising. The modifying agent may be a constituent of various oils or it may be any one of many other substances, including alkaline chlorides; it enters into the bubble-films between water and air, where the mineral particles are caught and held at the interface. The mineral-laden bubbles, arriving at the surface, aggregate into a froth, which is withdrawn, to be collected as a concentrate; this is drained, filtered, and dried previous to reduction by smelting in the ordinary way.

Is Turkey Disillusioned?

Altogether the most significant Mittel-European political news that has come in months was contained in a dispatch from Paris announcing an outburst of indignation in Turkey against her Teutonic exploiters. Had this dispatch come from Amsterdam or from Berne we would be disposed to consider it 'made in Germany' for foreign consumption, but it has filtered through France, and it bears the marks of intelligent comprehension of the Near Eastern question, such as may be found in official Paris. The young Turks are said to be conducting a bitter campaign in the press against Bulgaria, coupled with well-founded charges that Turkey was betrayed by the Central Powers in favor of their Balkan ally. Turkey sees no increase in her European prestige after having made heavy sacrifices, while Bulgarian aggrandizement has been carefully arranged by the Bucharest treaty of peace. Bulgaria is the potential friend of any Christian State, while Turkey is a friend-

less mongrel Moslem, of whose alliance no respectable country could fail to be ashamed. Therefore Germany considers that Bulgaria has her price, which must be paid, while she may risk the Turk's willingness to remain in the fold as a last hope against the extinction that he deserves. In this Germany may be mistaken. The old line of autocratic sultans understood the weakness of their political position better than the young Turks, who consider themselves progressives and therefore worthy of friendly support from countries committed to democratic ideals. The Turkish coin of democratic reform possesses only feeble resemblance to the real article; it is of exceedingly low fineness and is clumsily executed. Nevertheless, we cannot afford to neglect the opportunity to encourage the exasperation of the Turk against the Tonton, and it may be shown that his best chance for survival is found in the fact that the Allies are squarely on record against annexations, except in so far as they may be driven to complete occupation and administration of territory as an essential for winning the War. Old Abdul Hamid would have seen a less hopeful sign in the heavens than the star and crescent when the lower Euphrates valley fell into the hands of hostile powers. His forbears realized that no Eastern empire long endured that failed to hold the two extremes of Asia Minor. This is the tradition of Oriental autocracy, and the historic fact is likely to be recognized by the new Turkey. The power of Turkey lay in that strong position, but now she has lost her whip over European diplomacy, and Germany never will be able to re-conquer it. Even if she could she would not do it for Turkey, as recent events in the Balkans have demonstrated. It is certain that Turkey has a just grievance against Germany at this time; consequently the report from Paris is so plausible as to be regarded as a hopeful indication of the possibility of disrupting the Central European wall at the Bosphorus by means of skilful diplomacy. It would be interesting if President Wilson's refusal to declare war on Turkey should lead to this result. Fortunately for us the blundering Von Bernstorff is now the German ambassador to the Porte, and his record in Washington was one of such conscienceless duplicity that an Oriental more than any other would disbelieve his fair promises. We saw no symptom of a defection of Austria at the time when Count Czernin was making enigmatic peace proposals, because the political and financial circumstances of this wreck of the Imperium Romanum meant that the last chance of the ruling house lay in following the fortunes of the Hohenzollern. If Austria were detached, a group of new nations would emerge. The case of Turkey is different. She can save what is left, and be better assured of retaining it under a reformed administration, by cutting loose from Germany, and submitting her destiny to the progressive nations that are dedicated to the cause of civilization. Germany now has nothing in hand to offer her in trade without stirring the ire of Bulgaria. The chance for self-preservation and for commercial advantage through accepting peace with the Allies may prove strong enough to encourage a break with the Central Powers.

DISCUSSION

Pyrite From California

The Editor:

Sir—The writer has read the articles and editorial comments in the MINING AND SCIENTIFIC PRESS during the past few months with much interest, and the present discussion is based on the hope of creating a market not for any ores that I may control, but for the requirements and demand incident to manufacturers of war material and to increase the loading and forwarding equipment. I do not exactly agree with you that ships cannot be had from the U. S. Shipping Board. All the industries of the Pacific Coast must largely get the material from the East for fabricating into completed products. This material consists of plates, shapes, bars, and the like made at rolling-mills and furnaces in the East. The food products of the West are almost entirely shipped East by rail. One of the chief manufactures of the West consists of ships; these must have ballast. California does not produce sufficient tonnage to furnish such dead weight for ballast. Ores will supply the lacking tonnage. It is doubtful whether sufficient cars can be had to move the large tonnages of ore available, should the Eastern acid-makers accept what I maintain can be offered, namely, 30,000 tons monthly. That would require 500 cars per month, or 17 to 20 per day. An attempt must and no doubt soon will be made to relieve the demands the railways are staggering under, in their efforts to deliver heavy freights by means of ships, especially when delivery will be made to the consumer directly.

Improved Flotation Dryer

The Editor:

Sir—With reference to the interesting article appearing in your issue of May 11 on an 'Improved Flotation Dryer,' by S. Paul Lindau and W. S. Evans, permit me to say that this ingenious application of an old pan-conveyor has undoubtedly provided an excellent temporary solution for a pressing problem. Only those who have tried it know the difficulties encountered in drying flotation concentrate or like materials that are apt to be a sticky colloidal pulp. There are plants in the district mentioned where flotation concentrate is dried in shallow vats with steam coils where the cost of fuel per ton of concentrate much exceeds \$1, to say nothing of the additional cost for charging and discharging. Since it may be of interest to some of your readers, I am sub-

mitting a brief statement for comparison, with the cost of fuel \$1 per ton of concentrate, as stated by you in the subject of this discussion, and the cost of fuel at several installations using the Lowden patent dryer, as follows:

One plant is drying 56 tons (dry weight) of concentrate per 24 hours, having from 15 to 16% moisture in feed to 4% in the product, with $3\frac{1}{2}$ tons of coal at \$4.25 per ton, or 26c. per ton of concentrate.

Another plant is drying 30 tons (dry weight) of concentrate per 24 hours, with from 15 to 16% moisture in the feed to 5% in the product, with $1\frac{1}{2}$ tons of coal at \$4 per ton, or 23c. per ton of concentrate.

Still another plant is drying 31 tons (dry weight) per 24 hours of sticky colloidal concentrate, from 29% moisture in the feed to 13% in the product, with two tons of coal.

While the cost in the case of the Lowden dryer is given for coal, fuel-oil can be used. The choice of fuel would depend on the relative cost at the place of installation.

OSCAR REYNOLDS.

Denver, Colorado, May 17.

The Komspelter Indians and the Mexican Mining Law

The Editor:

Sir—Though I find little to criticize in your graphic account of the new developments of the Komspelter district, that little seems worth doing, as it seems to deal with something that is vital to the mining industry. It is perhaps as well for the Indians, as you state in your issue of March 2, "to take advantage of the opportunity given to them * * * by the U. S. government," as it would be for anyone else, but I refuse to consider that "a bountiful providence" can be a partner to this foolish transaction, or that "the energy of the white miner," who permits it to take place, can be considered "intelligent." Is not the catastrophe of the Great War a fitting time for us miners to take stock of the distributive as well as the productive side of our basic industry? How can an unearned 'royalty' paid to private individuals for permission to extract a living from raw mineral deposits be anything but a gross immorality, whatever may be the excuses mouthed by cunning pettifoggers to defend it? As students we were told that rewards in business are proportional to the industrial merit of the recipients, but your true story of the useless mucker, Hiram McBee, who gains more in a month from marriage to a land-owner than the cleverest mining engineer could usually hope to earn by a year's work, upsets the

romances of our school-days, and brings us face to face with anachronistic realities.

Politically considered, our laws regulating the ownership of mineral deposits are in direct conflict with the ideal of our institutions, which prescribes equal legal treatment to all citizens, because these deposits, being limited in quantity, can be given gratis to a few first-comers only by doing a gross injustice to the balance of the nation which is thereby deprived of its property rights in a national mineral resource. The favoritism is still more accentuated by the fact that a few mines only are very rich, and their owners are consequently more privileged by law than mine-owners as a class. It may be pleasant for the Commerce company to get \$5,000,000, and for P. N. Moore to gain \$500,000, also for various other speculators and Indian braves or squaws to be gathering up bushels of easy money without personal effort, but we may and must scrutinize the source of such windfalls, if we are expecting to do our duty by our generation and to make democracy safe for the world.

Before going further I beg leave to state the following economic axiom: 1. The value of mineral in the ground can be estimated by subtracting the cost of the labor and capital required for its extraction and marketing from its gross selling-price. 2. The cash value of an explored mineral deposit can be calculated by taking the present worth of its gross tonnage after assuming an average selling-price during the number of years required for total exhaustion. 3. Labor and true capital, that is, labor-products like tunnels, shafts, buildings, machinery, are active and competitive factors in production. Land (natural resources), constituting the remaining or third factor in production, is passive, and, being limited in quantity, is the monopolistic factor that tends to absorb the whole residuum of the wealth produced after the competitive returns of labor and capital have been paid.

For clear thinking, then, we must distinguish sharply between capital and land. In many districts, the relation of land to capital is complex. What part of a mine's earnings can be considered land rent (royalty) and what part interest on capital? In the Komspelter region, he who runs may read. Ben Quapaw never saved his pennies, as recommended by a leading Baptist, and yet he enjoys the income from four million dollars of savings, at 6% interest. Jim Good Eagle never worked an hour longer than the scheduled work-day—a popular recipe for getting wealthy—in fact, he probably never did a day's work in his life, and yet he is sporting a six-cylinder car; while Harry Crawfish and Julia Greenback did not miss success by anything more blame-worthy than failure to enroll themselves soon enough in the Federal agent's school for Indians who wish to get rich without working or saving.

Your criticism of the Mexican mining law, in your editorial of February 9, 1918, had some basis in its exposure of German intrigue, but I cannot agree with its strictures on Mexican land law as compared with ours. Under the former constitution of 1857, and the codes of 1884-1910, all metallic minerals were reserved to the Nation, while the constitution of 1917 reserves in addition

all non-metallic minerals. The metallic minerals can now be exploited only by individuals who have acquired a lease-title and pay an annual rent for their holdings, this rent being graduated according to area and varying from \$3 U. S. gold for claims under 10 hectares (25 acres) to \$12 for the excess area above 100 hectares. The annual rent on petroleum lands was fixed this spring at \$2.50 U. S. Cy. per hectare.

The effect of this stiff areal taxation is not to favor the rich, but rather to give the middle-class operator a chance, as the new rates are tending to break up the great speculative holdings that covered all the likely mineral ground in the country at the fall of Diaz in 1911. It is the middle-class man, not the peon, that must start mines here in this generation. The peon has not the initiative, the knowledge, nor the money to open a mine, no matter how low the areal tax might be reduced. Shame rather than undue modesty prevents me from claiming any responsibility for the new constitution, because it exhibits in so many places a deplorable lack of a consistent social philosophy, and yet I had probably much more to do with the creation of the famous Article 27 than had Lincoln Steffens, whose name you couple with that of President Carranza as a co-author. Indeed, about one-third of this long and revolutionary article of regulations governing natural resources can be traced directly to my book 'Latifundismo Mexicano; su Origen y su Remedio,' which was published by the Federal Department of Fomento in 1916.

Let us now return to our muttons, or rather, Komspelter, and apply the property ideas of the Napoleonic code, founded on the investigations made by the democratic scientists of the French revolution and now restored in their fullness to the mineral code of Mexico. The prevailing Komspelter system is practically the old Roman allodial tenure which considered god-made natural resources as absolutely private property as man-made clothes or buildings.

Supposing Oklahoma had had the Latin system and had reserved all minerals to the State. By an areal tax she could then prevent large speculative holdings at the very opening of a new zinc, oil, or coal district. Later, by taxing only the royalty-value of the mineral output, the State could set the operators free from annual fines for their capital expenditures and reduce the cost of living for laborers by the abolition of all kinds of taxation, increasing the price of commodities. If even 50% of the royalty-value of minerals were taken by taxation, it would still leave 50% as a premium to operators to cover their risk. However, the forestallers and the land-gamblers would find no more easy pickings under such a system, and as these gentry are cunning enough largely to control the press, the lawyers, and the politicians, we are not likely soon to see them working for a living. Some day the real producers, both operators and laborers, will cease chasing the rainbow of sudden riches through unearned increments and unite to introduce a mineral-land system that will ensure a square deal.

R. B. BRINSMADE.

Ixmiquilpan, Mexico, April 25.

Molecular Forces and Flotation

By WILL H. COGHILL

*Some of us are making an effort to ascertain the laws of nature and apply them to the flotation process, so that, some day, we may have not only an art of flotation, but also a science. Success will be achieved only through the co-operation of many builders, and it is the desire to aid in laying this foundation that prompts the publication of these notes.

THE PRINCIPLES OF THE DROP-WEIGHT METHOD FOR SURFACE-TENSION

Ferguson¹ states that 20 methods have been developed for the determination of surface-tension. The best known among these are the capillary rise and the drop-weight (weight of a falling drop) methods.

The numerical values obtained in surface-tension tests made by means of the capillary tube have always been accompanied by a shadow of doubt because of insufficient data on the contact-angle. Some investigators have boldly assigned a value to the angle at which the liquid meets the solid, and thus derived surface-tension from capillary rise. But Bigelow and Hunter² did not care to hazard so much. They expressed themselves as follows: "A liquid rises and is held at a definite height in a capillary tube through the action of two forces, first, the cohesion between the like particles of the liquid which, in the surface layer is denoted by the phrase 'surface-tension' and second, the adhesion between the liquid and the walls. The arrangement may be likened to a chain with two links, and when such a chain is strained to the breaking point it is the weaker link which gives away. So here, whichever is the weaker, adhesion or cohesion, must break first. The cohesion of a given liquid at one temperature must be considered as constant, not varying. We find the phenomenon of 'breaking' at different strains, therefore we must be measuring the force of adhesion. The force of cohesion must be greater in all our experiments, except those giving the highest results, and in those cases we have no sure means of knowing which of the two forces it is that gives way. Because of these considerations, we have intentionally avoided the use of the conventional values for surface-tension and have expressed our results in terms of the product of the radius into the height into the specific gravity, which is a measure of the weight held up, and leaves open the question as to what relation these values bear to surface-tension."

The drop-weight method for surface-tension determinations is probably the most reliable and destined to become the best known. It is based on what is known as the law

*By permission of the Director of the U. S. Bureau of Mines.

¹Ferguson, A., 'Science Progress', Jan. 1915, p. 428.

of Tate. Anyone who has standardized the tip of a burette by counting the falling drops to find how many are required for a given volume will grasp the significance of Tate's law, which is,

$$\frac{\text{Drop weight}}{\text{Tip diameter}} = \text{a constant.}$$

This formula has been brought out recently in a modified and workable form by Harkins and Humphrey³, to whom we are greatly indebted. In what follows I quote them freely.

Of these two methods (capillary rise and drop-weight) the first is much more sensitive to the action of impurities because the surface of the liquid involved in the measurement is made very small, whereas in the drop-weight method the surface is not only made relatively large but it is also renewed much more easily. It is not surprising therefore that the most concordant results on the surface-tension of a single liquid are obtained by the drop-weight method, and that duplicates run by this method, when it is properly applied, show a most remarkable agreement. However, when the results obtained by different workers on different liquids by this method are compared with determinations made by other methods, it is found that they show just as remarkable a disagreement, the deviation in some cases rising to 20% or even 40%. These bad results are due, however, not to any inherent fault in the method, but to the application of a faulty theory. Thus many workers have used the equation $W = 2\pi rT$ where W is the weight of the drop in grammes, and r the radius of the tip of the dropping-tube. This equation would be true only when the pendent drop is supported entirely by the surface-tension of the surficial film at the edge of the tip, and when all of the pendent drop falls, but this is far from the truth, for the drop that falls is not nearly all of the pendent drop.

The most complete treatment of the mathematical theory of the relation between the forms of drops and surface-tension is given in a book published in 1883 by Bashforth and Adams. Much later than this, in 1906, Lohmstein applied the general theory to the special case of the hanging drop just before its fall, and the residue left after the fall, and from the difference he obtained the magnitude of the falling drop itself. He arrived at the following expression:

$$W = 2\pi rTf\left(\sqrt{\frac{r'}{2T}}\right)$$

in which $f\left(\sqrt{\frac{r'}{2T}}\right)$ is a function of $\sqrt{\frac{r'}{2T}}$; d is the ef-

all dimension of 3.2 cm. has been found to give a convenient size. The tapering portion of the tip is a hollow shell, thin at the apexing end and increasing in thickness toward the shoulder. The inner conical opening is such that the tip will slip over the glass tip of the burette and fit tightly.

The cylindrical portion, at the end of which is the

the goose-neck and rolled in one direction to make a snug joint. All three tips are used in grinding the joint so that any one of them will fit.

Clean the burette thoroughly. A sodium dichromate-sulphuric acid mixture or ordinary washing-powder may be used. Rinse with distilled water and finally with alcohol, and let dry, keeping in mind all the time that a

PROP-WEIGHT APPARATUS FOR:		
<i>A</i> , Surface Tension.	<i>B</i> , Interfacial Tension, dropping downward.	<i>C</i> , Interfacial Tension, dropping upward.

dropping-end, is ground perfectly true, both along the length and the end, giving a sharp edge. A small opening runs the length of the cylindrical portion to allow the liquid to flow with ease from the burette to the dropping-end.

The outer cone of the tip is made to fit the flared end of the goose-neck by means of a ground joint. In order to get a tight fit, the brass tip after being rolled lightly in fine wet emery dust is inserted into the flared end of

small amount of some contaminants produces a great effect on surface-tension.

At the beginning of a test, the dropping-end should be polished lightly on fine emery-cloth, which is laid on a plane surface so that the edge of the tip will not be blunted. If the liquid to be investigated does not then spread readily over the dropping-end, it is essential that it be made to do so, which can be done by dipping in turpentine and re-polishing.

Before making a determination, two things should be ascertained:

(1) The value of a should be calculated from $\sqrt{\frac{2T'}{d}}$, then the value of $\frac{r'}{a}$. Of course the value of T' has to be determined by gradual approximations. Note that d is the effective density, that T' is expressed in dynes per millimetre, and r' in $\frac{r'}{a}$ is also in millimetres. The choice of tip depends upon this calculation.

(2) In interfacial tension tests, ascertain which liquid spreads more easily on the tip, because this determines which liquid is to be dropped in the other.

Generally a dropping rate of six drops per minute will give results that are sufficiently accurate, although Lohmstein's theory is based upon the assumption that the pendant drop is forming at an infinitesimal rate at the moment it breaks away.

The following is a numerical example:

Use the equation

$$T = \frac{W}{\frac{r'}{\sqrt{\frac{2T'}{d}}}} \text{ where}$$

W = weight of one drop.

r = radius of the dropping-end in centimetres.

T = surface-tension per centimetre in dynes, or grammes, depending on whether W is taken in dynes or grammes, respectively.

r' = radius in millimetres.

T' = tension in dynes per millimetre.

d = effective density, which in this example is unity.

W = 0.0915 gm. (using the smallest tip).

r = 0.3155 cm.

r' = 3.155 mm.

Determine the value of

$$\frac{r'}{\sqrt{\frac{2T'}{d}}} \text{ or } \frac{r'}{a}$$

by setting $2T' = 14.4$,

$$\frac{r'}{\sqrt{\frac{2T'}{d}}} = \frac{3.155}{\sqrt{\frac{14.4}{1}}} = 0.80 = \frac{r'}{a}$$

Now refer to the curve in Fig. 1 and find the value of $f(\frac{r'}{a})$ which corresponds to $\frac{r'}{a} = 0.80$.

It shows that $f(\frac{r'}{a}) = 0.618$.

The remaining part of the operation requires only a simple substitution to get the value of T , which is 0.0747 gm. (pure water). The assumed value of T' is so nearly correct that there is no need to repeat the calculation.

SOME SURFACE-TENSION MEASUREMENTS

A. W. Fahrenwald⁴ says: "While the film of oil on water may be only one molecule thick, or one twenty-five millionth of an inch, it will suffice to reduce the effective pull of the water from 73 to 43; this latter figure repre-

sents the effective surface-tension of water modified by oil as used in flotation."

It would be interesting if Mr. Fahrenwald would cite the research justifying the above numerical values. Though such figures have been used as a basis for a theoretical consideration, it is unlikely that they should be carried further.

It is thought that the following compilation of absolute values may be of interest since so much has been said about adsorption and its effect upon surface-tension. We have positive and negative adsorption, with a corresponding depression or elevation of surface-tension, depending upon whether the solute is concentrated in the surface or bulk, respectively.

In Fig. 3 are shown the surface-tension concentration curves for some of the liquids⁵ which are mutually soluble in water in all proportions. They give emphasis to Gibbs' law that a small amount of dissolved substance may reduce surface-tension greatly but will not increase it much, for, upon reading from left to right, and regarding alcohol or acid as the solute, we see that a small amount produces a marked change, and, reading from right to left and regarding water as the solute, it takes a large quantity of it to produce an appreciable effect.

Since the effect of sulphuric acid upon the surface-tension of water has elicited some comment in the literature on flotation, and, lest it be inferred that all surface-tension curves are as regular as those in Fig. 3, the tension-concentration curve for sulphuric acid⁶ in water is appended as Fig. 4.

Again there is a group of substances soluble in water in a limited degree whose effects have been determined by chemists. The effects of some of these substances—soap,⁷ phenol⁸ (carbolic acid), amyl alcohol,⁹ nonyllic (pelargonic) acid, and saponin,¹⁰ are shown in Fig. 5.

The surface-tension concentration curves of all of these, except sulphuric acid, is convex on the side toward the axes.

Another generalization is that of Valsen, namely, that equivalent salt solutions exhibit identical values of the surface-tension, even for varied concentrations. This is brought out by a comparison of Fig. 6 and 7. There would be indeed an approach toward coincidence of the

curves in Fig. 7, where concentration is expressed in relative number of molecules, if the temperature of the thio-sulphate and nitrate solutions were reduced to that of the chloride and chromate. If these coincided after this temperature correction, it would mean that at the same number of mols, or equivalents of any one of the four salts for the same number of mols of water, the surface-

FIG. 3

tension would be the same. Ionization, and possibly other factors, must be considered before this generalization becomes rigid and gives coincident curves.¹¹

Inorganic salts have been used in flotation, and sundry surface-tension effects have been ascribed to them by metallurgists. This is the chief reason for appending the above curves for inorganic substances. Note that the water, not the inorganic salt, is concentrated at the liquid-air surface, that is, the salt is negatively adsorbed.

FIG. 4

There is yet another group of substances whose surface-tension effect upon water should be considered, namely, the 'flotation-oils'. This effect has been overrated by Fahrenwald, and technical literature is replete with statements like the following by Megraw.¹² He explains that: "The primary function, which has been

¹¹Morgan, J. L. R., Schramm, E., "The drop-weight and surface-tension of molten hydrated salts, and their solutions", Jour. Am. Chem. Soc., Vol. 35, Dec. 1913, p. 1845.

¹²Megraw, H. A., "The Flotation Process", p. 39, 1916.

clear since the inception of the flotation process, is that the oil serves to reduce surface-tension of water and thus provide for bubbles and froth of more lasting character than could be formed without its use." Continuing, he says: "It seems evident, therefore, that in addition to the function of reducing surface-tension, which the oil undoubtedly does accomplish, there must be further work that it performs." I believe that the science of flotation is more likely to place the emphasis upon "further work"

FIG. 5

than upon a marked reduction of surface-tension of mill-solutions.

It seems strange, in view of all that has been written about surface-tension, that there are no published data on the absolute values of the surface-tension of mill-solutions. E. H. Miller, of the U. S. Bureau of Mines, has recently made a series of such tests with the Minerals Separation laboratory type of machine. The results place the oils in two groups with an arbitrary dividing

FIG. 6

line of 65 dynes, and 0.1% oil. The effects of those oils of the first group, namely, those that give a surface-tension below 65 when present in the ratio of 1 to 1000 parts of water, are shown by curves in Fig. 8. In each test, water, to which a known amount of oil was added, was agitated for 10 minutes and filtered, after which the surface-tension was determined by the drop-weight method. The maximum effect as indicated on the drawing gives the tension of the water when contaminated under an arbitrary condition, to wit, where the oil and

water, in a ratio of 1:1, stood in contact for one hour. This "maximum effect" is an interesting property of many oils that, though they do not affect the tension when used in commercial quantities, have a small percentage of constituent soluble in water, where it is positively adsorbed. Several tests were made in the presence

FIG. 7

of ore, and since the ore seemed to have no effect upon tension it was subsequently omitted.

The second group is shown in the accompanying table. The maximum effect only is noted because the surface-tension effect when used in working quantities was so small that it could not be satisfactorily determined with the available apparatus.

Note that 75% of the flotation-oils investigated fall in the second group.

The maximum surface-tension effect of a series of 'oils'

The determinations are the result of rapid work with crude drop-weight apparatus. They should be regarded therefore as a preliminary survey of the physical properties of flotation-oils.

An attorney once discoursed at great length upon

FIG. 9

surface-tension and said that the longevity of a bubble was increased by decreasing the contractile drawing force of surface-tension. It is hoped that metallurgists will never again allow such fallacies to be flaunted in their way by the legal fraternity without offering due challenge.

PROOF OF SURFICIAL CONCENTRATION OF A DISSOLVED SUBSTANCE

It was stated above that the difference in concentration between the surficial layer and the bulk of the solution is amenable to demonstration. Three of the best known proofs are the color test, chemical analysis, and drop-weight analysis.

A demonstration of the color test can be made in a few

minutes by shaking a dilute water solution of methyl violet in an elutriating flask and drawing off the bulk of the liquid through the stopper while the froth remains in the flask. After a few repetitions the difference in concentration is apparent by the color.¹³

The proof of adsorption by means of chemical analysis was probably the first one applied. The method is outlined in the following by Taylor.¹⁴ He says: "The experimental demonstration of the equation, which was first derived by W. Gibbs in 1876-78, was long in being realized. In 1896 the author, working in Ostwald's laboratory, observed that the electric conductivity of a dilute aqueous solution of sodium oleate changed when the solution was stirred up with the electrodes, so as to produce foam on the surface, and gradually returned to its initial value as the bubbles slowly collapsed. This could be repeated as often as desired. Attempts to separate the foam on a large scale, in order to prove the difference by analytical methods, were unsuccessful. Zawidzki (1900) effected the analytical proof in the case of salts and acetic acid by the simple expedient of adding saponin, and analyzing the foam carried over by bubbles of air. The differences in concentration were considerable. Miss Benson (1903), working with aqueous amyl alcohol, which, like soap solutions, does not require extraneous substances to produce foam, found the surface concentration to be 0.0394 n., the original concentration being 0.0375 n."

Drop-weight analysis is beautifully adapted to prove adsorption when the solute has a marked effect in reducing surface-tension. In a certain test where 500 gm. of ore was treated in the mechanical agitation type of machine with 4500 gm. of water and 0.12 gm. (0.003%) of Floteo No. 1, to float chalcopryrite, the tension of the overflow liquid (175 gm.), which was collected in the form of a froth and had therefore an enormous surface, was 69.3 while the tension of the underflow (4325 gm.) was 71.8. In another test where the solution samples were taken near the end of the run, and extra oil had been added to substitute for the solids that stabilized the froth during the first part of the run, the tensions of the overflow and underflow were 65.9 and 69.8, respectively.

This soluble oil was therefore concentrated in the overflow in accord with tests made to prove adsorption, as given in textbooks on colloid chemistry. Further, the percentage of oil in each product may be read off from a predetermined surface-tension concentration curve; this is drop-weight analysis, and it has not received sufficient attention in our laboratories.

NICKEL prices have been agreed upon between the International Nickel Co. and Bernard M. Baruch of the War Industries Board, the prices being 40c. per pound for the highest grade and 38c. for the lower grade.

¹³A pure methyl violet froth lacks the stability necessary for this separation, but this defect may be remedied by a trace of saponin.

¹⁴Taylor, W. W., "The Chemistry of Colloids", p. 235, 1915.

Minerals Separation v. Butte & Superior

Following the opinion handed down by the U. S. Circuit Court of Appeals, which was published in the MINING AND SCIENTIFIC PRESS on May 25, an amendment to the decision has been made in view of the fact that the Butte & Superior company, by its own admission, had used 0.5% or less of oil per ton prior to January 7, 1917. The supplementary order modifying the decree is given below:

"Ross, Circuit Judge, Hunt, Circuit Judge, concurring, Morrow, Circuit Judge, concurring in the reversal but dissenting from the modification of the decree herein directed and as to costs:

Understanding from the presentation of this case that the real and pivotal question for the decision of this Court was whether or not under the decision of the Supreme Court in the case of Minerals Separation, Ltd. v. Hyde, 242 U. S. 261, the use of any oil by the appellant in quantity of one per cent, or less on the ore, constituted an infringement of the appellees' patent, and that the fact was undisputed that the appellant had not used as little as one-half of one per cent of oil in its process, in reversing the judgment of the court below we directed that court to dismiss the bill at the complainant's cost. Inasmuch, however, as it appears and is admitted that prior to and including January 7, 1917, the appellant did use in its process oil in quantities of one-half of one per cent and less, thereby in those instances infringing the patent of the appellees,

It is hereby ordered that the judgment of this Court herein rendered and entered May 13, 1918, be and hereby is corrected so as to read as follows:

The decree appealed from must be and is reversed and the case remanded with directions to the court below to so modify its decree as to accord with the opinions of the majority of this Court—the appellant to recover its costs on this appeal."

THE BRITISH GOVERNMENT is taking steps to exploit the deposits of monazite sand recently discovered by the Imperial Institute mineral survey, and the necessary plant is being shipped. Thoria, produced from this mineral, is extensively used in the manufacture of incandescent-gas mantles. Previous to the War the only deposits of importance were found in Brazil and India, both sources being in the hands of Germans, the monopoly being used to further the sale of Welsbach and other German mantles. The Indian mineral contains a higher proportion of thoria than the Brazilian monazite. The Ceylon survey has also shown that the island contains deposits of thorium, the most valuable mineral of this class. The available amount is limited but the product has been marketed in London at over \$8000 per ton.

PYRITE importations will be cut down gradually, under orders from the War Trade Board, until the minimum of 10,000 tons per month is reached in September. During 1917 this country imported from Spain 747,830 tons of pyrite, and from Canada 210,615 tons.

Concentration by Dense Solutions

By THOMAS M. CHANCE

*All gravity methods for the separation of ore from gangue, or of slate and other refuse from coal, are based upon differences in the falling velocities, in some fluid medium such as air or water, of the materials to be separated. As all materials falling in a vacuum have the same velocity, independent of the size, shape, weight, or specific gravity of their individual particles, it would be more accurate to describe the operation of these methods as depending upon the retardation of falling velocities effected by the resistance of a fluid medium, this retardation being greater for small or light particles than for large or heavy particles.

The separation of materials of different specific gravities by means of a fluid having a specific gravity greater than that of the lighter particles and less than that of the heavier particles has not been applied commercially, or on a large scale, to the separation of ores or to the washing of coal. The method has been limited to laboratory experimental work or to laboratory determinations for the purpose of checking up the work of jigs, classifiers, and other types of concentrating appliances. A solution of zinc chloride has thus come into general use in the laboratory to separate coal, bony coal, and slate, both to check up the work of coal-washing plants and for the purpose of making tests preliminary to the designing of coal-washing plants. The use of a heavy solution of some chemical in water has often been proposed for making such separations, especially in connection with the washing or preparation of coal. Practically insuperable difficulties, however, have prevented the commercial development of any such process, the difficulties being both physical and financial. The cost of the chemical used to make high-gravity solutions is usually prohibitive, and the freeing of the coal from all traces of the chemical is found to be practically impossible.

The method which it is the object of this paper to describe is based upon the facts that any relatively finely comminuted insoluble solid matter, such as sand, if mixed with a certain quantity of liquid, such as water, can be maintained suspended in the liquid by continuous agitation, and that the mixture, so long as agitation is maintained, will form a mass exhibiting physical properties similar to those of a fluid of relatively high specific gravity, including its ability to float solid bodies having less specific gravity, while permitting solid bodies of greater specific gravity to sink. The agitation of such a fluid mass may be effected and maintained by any suitable mechanical appliance, or by introducing liquid under pressure as jets or as a slowly rising current. When a fluid mass of a certain predetermined specific

gravity has been produced in this manner, its specific gravity will remain constant so long as the agitation applied to it is not varied. The specific gravity of the fluid mass will be diminished by increasing the agitation, provided the necessary additional liquid is supplied for dilution of the fluid mass; while its specific gravity will be increased if the agitation be diminished. I have found that a mixture of sand and water can be used to produce a fluid mass having a specific gravity suitable for the separation of coal from bony coal, slate, fireclay, pyrite, and other impurities, and have used sand ranging from 20 or 30 mesh down to 100 or 200 mesh, or finer, and find that fluid masses with specific gravities ranging from 1.20 to 1.75 are easily produced and can be maintained constant for an indefinite period at any desired gravity within these limits.

I have found also that fluid masses having a specific gravity high enough to float quartz, feldspar, limestone, and other rocks, can readily be produced by using magnetic iron-ore sand and water instead of quartz sand and water. Other heavy materials can be used, such as ore concentrates of galena, or metallic copper, for producing fluid masses having very high specific gravities.

For the practical separation of materials of different specific gravities by this method, the following observations are evident: (1) Every particle of material having a lower specific gravity than that of the fluid mass will float; that is, the separation will be independent of the size of the materials to be separated. If the fluid mass be contained in a receptacle large enough to permit the introduction of large lumps, it is possible to dump the ore or coal, as mined, without any preliminary sizing, whereupon, every particle of less specific gravity than the fluid mass will float, irrespective of its size or shape. (2) As every particle of material, irrespective of its size or shape, having greater specific gravity than the fluid mass will sink, no preliminary sizing is necessary to insure the sinking of all material having a higher specific gravity than that of the fluid mass. (3) The insoluble material, such as sand, used for producing the fluid mass, can be washed readily from the materials which have been so separated, and thus can be recovered and returned to the fluid mass for continuous use.

This method offers facilities for making differential separation of materials which may be of nearly the same specific gravity, because the fluid mass can be so adjusted as to float one material while permitting the other to sink, although the difference between their specific gravities may be slight. This characteristic can be applied to the separation even of low-ash from high-ash coal, of coal from bony coal, or of bony coal from slate; and with ores it may be utilized for separating waste rock from rock that contains sufficient ore to justify crushing and concentration, as well as for the separation of ore-bearing minerals of different specific gravities.

The development of this method has been so recent that it has not yet been introduced commercially, attention having been directed wholly to perfecting appliances suitable for its practical application.

*Abstract: A New Method of Separating Materials of Different Specific Gravities, February 1918 meeting, A. I. M. E.

The Calico District, California

By LEROY A. PALMER

INTRODUCTION. The Calico mountains are situated in the western part of the Mojave desert in San Bernardino county, California. They extend along the north side of the Mojave river from near Daggett, the junction of the Salt Lake and Santa Fe railroads, to a point opposite Barstow. The main portion of the range, which is the only part that contains mineral deposits of economic value, lies north of the old town of Daggett and of the newer town of Yermo, a division-point on the Salt Lake route four miles from Calico. This is one of the few silver-mining centres of California.

HISTORY. While the days of the greatest activity are not so remote but that undoubtedly there are men living who recall them, I did not find anyone who could speak authoritatively on the subject. There were two towns, Calico, the silver producer, which was by far the larger, and Borate, at the borax mines. There was also a small settlement, West Calico, in the vicinity of the Waterloo mine, about two miles south-west of Calico. The first discovery of silver ore was made at Calico about 1880. The town grew rapidly, several mines became productive, and the district attained great prosperity in the late 'eighties. The population grew from 1000 to 4000. It is probable that, in the time of greatest activity, there were about 700 miners engaged at this point. The district then was reached by two railroads from the Santa Fe line at Daggett; one forked near the foothills, branching to the Waterloo mine and to a point near the town; the other was built with three rails, for standard and narrow gauge, as far as the borax mill, and thence as a narrow gauge up Borate canyon to Borate. In 1885 application was made through the Superior Judge of San Bernardino county to the Government for a patent to the townsite of Calico. This could not be granted immediately as the site chosen had never been officially surveyed. The application was placed on file, and when the surveys were made some years later the site was tied in, platted on the official maps, and notice sent to the presiding superior judge that patent would issue as soon as certain minor requirements were fulfilled. To this notice the judge replied that there was no longer any necessity for a patent, as the town of Calico had ceased to exist, not a single resident remaining. During the late 'eighties about a dozen mines continued to produce, and at least half-a-dozen mills, some having as many as 60 stamps, were in operation. The ores contained chlorides and bromides of silver, which were treated by pan amalgamation. The bullion produced was exceptionally pure, 990 fine being common. The two larger companies became involved in a long and expensive litigation, and soon after came the 'silver panic' of 1893. The operators at Calico

did their best to weather the storm, but the financial crisis brought ruin, and the mines were abandoned to lessees. Desultory production persisted until 1897. Since then the only sign of life has been an occasional chlorider hunting bunches of high-grade that might have been overlooked. At the time of my visit, in February 1918, there were five men at work.

GEOLOGY. The Calico range extends several miles along the north side of the Mojave river as a series of detached mountains of moderate height broken by intervening valleys and plateaus. The name 'Calico' was given because of the great variety of color from lava flows and sedimentary beds of distinctive hues, which, in the shifting rays of the sun, are multiplied and exaggerated. The portion of the range that is of economic interest extends due east and west about six miles, with a maximum

SOUTHERN CALIFORNIA. CALICO IS IN SAN BERNARDINO COUNTY

width of less than three miles. Of this area W. H. Storms¹ said: "The geology of the Calico mountains at first sight looks simple enough, but a more thorough investigation quickly convinced me that there were structural problems to be studied of more than passing importance." My own conclusions coincide with those of Storms, to which I may add that the region is to be recommended for ideal illustrations of the phenomena accompanying eruptive action.

ERUPTIVES. The principal rock in the vicinity of the town of Calico is rhyolite, appearing as a series of flows and effusions. Massive rhyolite exists in many forms and in a great variety of colors, the most prominent being a reddish purple; it is also found in sombre tints, from

¹'Calico Mining District,' 11th Rep. of California State Mineralogist.

brown to black, and dark to brilliant green. The massive forms generally show quartz with the aid of a good lens. In the earlier flows the rock is massive, dense, and fine-grained. The later flows show breccias spotted with angular pebbles of the same composition as the ground-mass, and among the higher flows are porphyries, with well formed and easily recognizable phenocrysts. True conglomerate was observed rarely, but there was one example of a good-sized chunk of granite embedded in the rhyolite.

Numerous craters of remarkably uniform shape were found. Flow-structure is prominently developed in the massive rhyolite. The flows dip in opposite directions—north and south—from the summit of the range. Regular jointing is seen, but columnar structure is wholly absent, as would be expected in a rock so acid. There are numerous features that tend to show that the mass was erupted in a highly fluid state. In one ravine, I found a low perpendicular face in which is a small cave, formed when the crust of the lava became chilled and stiff, while the warmer and more fluid portion beneath flowed onward and left an arching roof over a small room about three feet high. The lower portion of this roof had remained pasty, and molten lava dripped from it in spots, forming stalactites, from which lava dropped to the floor until, in some cases, the stalagmites met the stalactites and formed lava-columns.

The tuffs likewise are interesting. They are principally white and light-yellow to buff. Their most notable occurrence is along the summit of the range, where they are frequently found as breccias enclosing fragments of the massive rhyolite. Stratification is distinct in many localities and, unless the beds have been displaced, the dip is north or south, away from the crest.

The character of the rocks is markedly reflected in the topography. Save for a few scattered outliers the soft tuffs, which presumably covered the entire country at one time, have been eroded, except from the higher portions of the range. Removal of the tuffs exposed the massive rhyolite, which yielded to erosion much more slowly, and with comparative uniformity, except where a gulch or canyon marks the course of a stream. The tuffs, on the other hand, exhibit pronounced differential erosion, as a result of which they form sharp spires and castellated crags, intersected by precipitous canyons. Undoubtedly the eruptives are very young. Lindgren² says they are probably of early Pliocene age, but he does not state on what he bases this conclusion other than "the form of the mountains, the often occurring craters, and finally the great masses of tufas give evidence in favor of their comparatively recent origin." Storms³ fixes the age of the Calico uplift as probably Oligocene. The eruptives are certainly Tertiary and probably belong to the later portion of that age.

SEDIMENTS. In the western part of the district the sediments form a belt surrounding the foothills. In the

eastern part they extend much higher up the mountain-slope and are more widely distributed. Clays and sands predominate, but intercalated with them are strata of tuff, thin sheets of lava, principally the purple variety of rhyolite, occasional chert and jasper, small beds of conglomerate and breccia, and occasional limestone. Pack⁴ described these beds in considerable detail, as he found them in the Barstow syncline some miles to the west. He classed them in three divisions, having a total thickness of at least 3000 ft. These divisions are reproduced at Calico, but I would not venture an opinion as to their thickness. The character of the beds has a marked influence on the topography. Going up Borate canyon from the valley there is first a region of moderate relief, consisting of shallow gullies and rounded hills. Farther

CONTORTED LAKE-BEDS

up are many steep-sided gulches of considerable depth, presenting a typical illustration of 'bad land' topography. The uppermost portion of the sediments presents again a region of moderate relief.

STRUCTURE. The locality has been described by Lindgren and Storms, but their conclusions are not entirely in accord. My own agree in part with each. Lindgren refers to the rhyolites and tuffs "together with the clay and sand strata derived from them." Storms says, "the lake sediments were from some other source than the Calicos, as they are found on the high ridges and peaks," and again he speaks of the "heavy accumulations of detritus in the shape of clays, sandstones, conglomerates, and breccias whose constituent parts were almost all derived from the disintegration of earlier volcanic eruptions." The statement that the sediments are found on the high ridges is true only of the region about Borate, where a fault, which shows plainly from the valley, and which strikes somewhat west of north, has an upthrow on the east so that the lake-beds on that side appear at a much greater elevation than on the west. I am of the opinion that the existing structure can be accounted for as follows: Deposition of the sediments was contemporaneous with the volcanic extrusions spread over the bot-

²"Silver Mines of Calico, California", by Waldemar Lindgren. Trans. A. I. M. E., Vol. 15.

³Loc. cit.

⁴"The Barstow-Kramer Region". H. W. Pack, U. S. G. S. Bull. 541.

tom of an extensive lake. This is indicated by thin beds of rhyolite intercalated with the sediments, and perhaps by the intercalated tuffs, although the latter may have been eroded from some higher point. As volcanic activity increased the mountains of lava, breccia, and tuff were built up, and the sediments, derived in part, no doubt, from the erosion of this mountain mass, continued to deposit about it until the waters of the lake in which this

tion by lessees has shown the existence near West Calico of a vein in which the principal metal is gold. The silver ores were found in, or related to, the zones of structural weakness, and also as irregular pockety deposits. Whereas the trend of the fractures is mainly east and west, toward the western portion of the district they swing toward the north. Some of the veins were in fissures, with well-defined and clean-cut walls, in places with pronounced slickensiding, but it

CALICO, CALIFORNIA

action was taking place had subsided. Finally adjustments of the surface took place, accompanied by faulting and folding, which brought the volcanics and the sediments into still more intimate relationship. The igneous rocks yielded by faulting and crushing, while the softer sediments gave way preferably by folding. The sediments consist of many thin beds. Although some of them, such as the lavas, cherts, and jaspers, and some of the sandstones, are hard and brittle, the individual strata are thin and are cushioned by the intercalated sands and clays, which are soft and plastic. This forms an ideal condition for deformation without fracturing. The sediments present some of the most highly distorted forms that I have ever seen. The trend of the folds is mainly along east-west axes, corresponding to the major fractures in the rhyolite, but there are many minor and complex folds, indicating that the pressure was applied from many directions.

ORE DEPOSITS. The ores of the district are of two kinds chiefly, chlorides and bromides of silver at Calico, and colemanite (borate of lime) at Borate. Recent explora-

tion by lessees has shown the existence near West Calico of a vein in which the principal metal is gold. The silver ores were found in, or related to, the zones of structural weakness, and also as irregular pockety deposits. Whereas the trend of the fractures is mainly east and west, toward the western portion of the district they swing toward the north. Some of the veins were in fissures, with well-defined and clean-cut walls, in places with pronounced slickensiding, but it is probable that true fissure deposits were not as common as those formed in fracture-zones. These zones accompanied the faulting, consisting of series of parallel main fractures crossed irregularly by innumerable smaller ones. The channels thus formed were sealed by deposits from mineral-bearing solutions, which were undoubtedly ascending, and the result was a stockwork so intricate that it was necessary, in most cases, to mine and treat the entire mass to recover the valuable mineral. The gangue was

BAD LANDS IN LAKE-BED FORMATION

principally quartz and barite, with subordinate amounts of iron and manganese oxides, and lead carbonate. Recent work by lessees shows an increase in the amount of lead carbonate in some of the veins. The veins vary in width from that of a knife-blade up to 10 ft. or more, averaging about three feet. The deposits along the fracture-zones were irregular; sometimes only a small pocket was found; again the orebody would yield a large stoppe. The pocket deposits were found in the tuff near the surface. None of these came directly under my observation. Lindgren describes them as containing the

same ores as the fissure (and fracture) deposits, not far distant from them, usually lower, and sometimes following the bedding-planes of the tuff; hence, he concludes, they are doubtless overflows from the fissures and fracture-zones.

Schrader* has stated that there are a number of mineralized districts of strikingly similar formation extending from Oatman, Arizona, to the longitude of Barstow, California, and he cites the Calico mountains as one of them. A comparison of the eruptive portion of the Calico with the Oatman district is interesting. The formation at Oatman is a pre-Cambrian complex followed by metamorphosed Paleozoic limestones and shales, and by flows and effusions of Tertiary andesite and Quaternary basalt. Considering these in reverse order at Calico, the basalt, which is wholly post-mineral, is lacking. In place of the andesites are rhyolite flows and tuffs. Here the similarity ends, but about ten miles farther north, in the Goldstone district, are limestones and shales, uncorrelated but unquestionably pre-Tertiary. Still farther north, above Goldstone, are granite mountains, but I cannot state their relations to the limestones and shales. It should be noted, however, that at least one occurrence of fragmentary granite was observed in the rhyolite at Calico. At Oatman there were at least two periods of parallel fracturing. The first opened fissures in the andesite, which were sealed by calcite veins. The second fractured the calcite veins, permitting the circulation of silicious solutions and the replacement of the calcite by quartz. At Calico there was undoubtedly more than one period of fracturing, as shown by the parallel breaks and by the numerous minor fractures associated with the mineral deposits, and this fracturing was prior to the ore deposition. These points tend to confirm Schrader's conclusions, and indicate an interesting similarity between the two districts.

BORAX. The borax occurs as colemanite, $\text{Ca}_2\text{B}_6\text{O}_{11} \cdot 5\text{H}_2\text{O}$. Many thin seams of unworkable thickness of the 'cotton-ball', as the miners call it, are found throughout the sedimentary beds. The workable deposits near Borate present two exposures, which can be traced along the hillside for nearly two miles. Beyond this the quality is poor and the thickness diminishes. Campbell† found the thickness of the beds to range from 5 to 30 ft., and he stated that there was some doubt as to whether the two outcrops mark different beds or result from a sharp fold. The average thickness of the beds now being mined is approximately five feet. Development has not yet settled the question as to the identity of the beds. Storms gives it as his opinion that the colemanite was formed as a residual deposit from the evaporation of water containing calcium borate, the deposition taking place in a basin, which was cut off from a larger lake by the recession of the waters. This is the generally accepted theory as to the origin of saline and similar deposits, but Gale‡, in discussing the origin

of a sedimentary deposit of magnesite in similar strata, and in the same topographic basin as the borax beds, having lime in the same series, advances the theory that the deposition may have been the result of reaction between magnesian and lime-bearing solutions, the one existent in the water of lakes and the other fed to it by springs. The colemanite is sorted, and with reasonable care a product containing more than 60% boric acid is obtained. Across the range from Borate in the valley is an extensive deposit of 'mud borax', that is, colemanite mixed with the sand and clay of the lake-beds so as to carry only about 15% boric acid. Several attempts have been made to work these deposits, but none has yet been successful. One company conducted operations on an extensive scale and expended a considerable sum of money unprofitably.

ECONOMIC CONDITIONS. The future of the district is by no means certain. At most of the mines the high-grade ores were exhausted, but the ordinary 'chlorider' does not hurt himself by hard work and yet appears to make a living, so there may be deposits that will pay for small-scale leasing if carried on systematically. I received fairly credible reports that a large amount of ore containing five to six ounces of silver per ton still remains. If this be true there is a chance of renewed activity at the prevailing price of silver. The mines were worked apparently in an unsystematic manner, without thought of the future. Timbers were costly and were used sparingly, even in the larger stopes. The old dumps from the mills, aggregating many thousand tons, are worthy of consideration. Two years ago a cyanide plant was built to treat the tailing of the old Runover mill, but the attempt was not successful. This was considered to be due to the faulty character of the mill and its operation.

Calico is only four miles from Yermo, on the main line of the Salt Lake Route, and is connected with it by a good road. Motor-truck haulage should not be expensive. Water is to be had in the valley within 50 ft. of the surface, and was obtained from that source and pumped to tanks above the town when the district was active. Recent developments at Borate lead to the conclusion that these deposits are not as near exhaustion as they were once supposed to be. They are controlled by the Pacific Coast Borax Co., which holds patent to all the land on which known deposits of economic value exist.

SULPHURIC ACID is quoted by dealers at \$60 per ton for the 66° B. grade, and 60° acid brings \$55 per ton. Manufacturers are out of the market, and are not accepting new business except where orders are accompanied by a Government requisition.

HYDROCHLORIC ACID is showing greater activity, owing to an increased demand by the Government. The price for 18° acid in carboys is 2½¢. per pound; for 20° acid 3¢.; and for 22° acid 3½¢. spot.

Man-Power

By J. PARKE CHANNING

*We are accustomed to think that we are efficient in the United States, particularly with respect to such things as mining and manufacturing. The conduct of the War has demanded in England and in France a complete readjustment of manufacturing methods and plans, and today England is probably as efficient a country as there is in the world, not even excepting Germany. This is all the more remarkable because it has been notorious for years that England has been inefficient in her manufacturing and the country has been flooded with things 'made in Germany.' Today England is almost a socialistic community and the State is doing almost everything. England is now in such a position that practically everyone in the country is engaged in industry necessary for the conduct of the War, and this has been accomplished by increasing the efficiency both of her tools and of her man-power.

In the United States we certainly have been efficient so far as machines and perhaps so far as methods have been concerned, but we have not been efficient in the utilization of our man-power. Before the War, our labor was undoubtedly far more efficient than that of England, but it certainly was not so highly efficient as it should have been, and the problem that confronts us today, and will all the more confront us after the War, is to make our man-power efficient. England has had a taste of what you may call state-socialism, and her laboring men are not going to be content to return to the old order of things. There is one feature of the labor problem in England which has permitted her to reach this condition of state-socialism with comparative rapidity; this is that practically all of her laborers are English; she has little or no foreign population. While an Englishman may be a strong union-man and ready to fight his employer tooth and nail, at heart he is still a British subject, and when his country was in danger he rose to the occasion.

In the United States we have such an admixture of unassimilated foreigners that the problem is more difficult, and as yet we have not been brought to that point of stress which has arrived in England. But if we are to carry the War to a successful conclusion, and if we are to increase our efficiency after the War, we must introduce methods which will Americanize these foreigners and give them our own point of view. We have been called the 'melting-pot', but it is a question whether even our melting is efficient, and whether at the top of the crucible there does not accumulate too much dross and at the bottom not enough clear alloy.

I wonder if any large number in this country have

read the so-called reconstruction program of the British labor party. It will, of course, be subject to a great many modifications before it is adopted by the party, and no doubt still further and greater modifications will be made before any or all of it is accomplished. It is largely socialistic and has for its basis four principles or pillars, as they choose to call them, of the house which they hope to erect. These four pillars are:

1. The universal enforcement of the national minimum.
2. The democratic control of industry.
3. The revolution in national finance.
4. Use of surplus wealth for the common good.

If these four demands are carried out, then surely England will be a socialistic State.

I am not prepared to say how much of this program can, or will, be carried out, but it shows the trend of thought of the laboring man in England. He has seen his wages increased so as to keep pace with the growing cost of living, he has seen the profiteer discouraged, and he is more than ever convinced that in the past he has not been getting his fair share of the product of his toil; and, I believe, at the same time he is realizing that undoubtedly in the past he has not done his proper share in increasing the wealth of the country. Nor can he be blamed for this, because, seeing large fortunes grow up before his eyes, while he gets but a small proportion of it, the incentive to increased efficiency has not been great. He realizes that when the War is over, unless the greatest care is used in the re-organization of the regular industries, there will be an immense amount of unemployment; that this, if unchecked or uncared for, will result in an over-supply of labor, and, if the old standard is maintained, a corresponding diminution in wages. This he feels should not be; hence his insistence of the first principle of a minimum wage. And the minimum wage that he asks for is certainly not a high one, being 30s. or, we will say, \$7.50 per week.

In demanding democratic control of industry he has observed such good results attained in war work that he sees no reason why this control of industry should not be just as efficient under after-war conditions.

In the third pillar, the revolution in national finance, he demands that taxation shall be so adjusted that it will yield the necessary revenue to the Government without encroaching upon the prescribed national minimum standard of life of any family whatsoever; without hampering production or discouraging any useful personal effort, and with the nearest approximation to equality of sacrifice. Apparently he is not a protectionist and repudiates all proposals for a protective tariff; however, this may be disguised. In this point they agree with Courtenay De Kalb, a prominent mining engineer.

*Presented at a meeting of the Boston Section of the American Institute of Mining Engineers, March 15, 1918.

who, in the December 1917 number of the 'Atlantic Monthly', has a most excellent article on the 'Formula for Peace,' in which he states, that, if after the War we can have an industrial world in which there are no protective tariffs and no subsidies, in which every nation is engaged in producing those articles for which it is best adapted, that then there will be less incentive for war.

The fourth pillar of the English laborite is that the surplus wealth shall be used for the common good. They say that we have allowed the riches of our mines, the rental value of the land superior to the margin of cultivation, the extra profits of the fortunate capitalists, and even the material outcome of scientific discoveries, to be absorbed by individual profiteers, and he demands that in the future a large proportion of this surplus shall be applied to the common good.

You must realize that the English labor party is not like the Bolsheviks of Russia. It is not carried away with the beliefs of Lenin and Trotsky, that the proletariat are the men to manage the country. The English laborer frankly realizes the importance of brains and education, and admits that the highest success of the country cannot be obtained without the aid of those who plan, and manage, and invent, nor would he object to allowing these men to get their fair share of the profits. Evidently the class against which his program is aimed is comprised of those more or less sharp and shrewd men who, without anything more than commercial ability, of themselves reap the advantages of the brains and muscles of others.

It is not for me, nor am I a sufficient student of economics, to pass upon this program. It has certain merits, and I am calling it to your attention only that you may see that just this same thing is liable to come up in the United States. And the trouble will be that the pendulum will very likely swing too far if the employer class in the United States does not give more attention to the laborer and see that his condition is improved. You, as engineers, are in the position to act as the instruments for carrying out this necessary work. Whether it be in a mine or a manufacturing plant, I believe I can say that today a large proportion of the managers and executives are engineers, and the proportion is constantly increasing.

The question to be clearly faced is, are we properly trained to bring about this improvement in our social conditions, to improve the living conditions of our laborers and at the same time to improve their efficiency. I fear that a great many of us are not. We may be good technical men but we are not sociologists nor psychologists. We understand production of kilowatt-hours from coal or from water-power, we understand the machine by which it is utilized, but we do not understand the machine which produces our man-power.

I recently attended a conference at Columbia University, at which the question of giving the engineering students a course in human engineering was discussed, and I came away with the idea that the authorities were beginning to realize that this was of paramount importance and that this training must be given the engi-

neering student before he can be turned out as a man capable of eventually holding a high executive position. Many of the students have the ambition to hold high positions, but at the same time, in the most naive manner, announce that they have no desire to have anything to do with the working-men themselves. In my opinion, there never was a time when it was so necessary to impress upon engineers and engineering students the importance of this human side of engineering.

I wonder how many of you can tell me what trade-unionism is—you who have had to deal with unions and have had strikes? The fact is that none of you can tell what trade-unionism is because trade-unionism is not an entity but a term of broad generalization covering a great many distinct aspects of the labor problem. Some of you who, perhaps, are railroad superintendents, whose knowledge of trade-unionism is based upon your contact with the Brotherhood of Locomotive Engineers, would give one definition; others, who have been managing a mine in the Rocky Mountains, whose contact has been with the Western Federation of Miners, would give another definition. Specifically each of you would be right from his own point of view, but neither of the definitions would cover trade-unionism as a whole. A few weeks ago I might have been rash enough to attempt a definition, but in the meantime I have read Professor Hoxie's work on 'Trade Unionism in the United States,' and my ideas on the subject have been much clarified. I would advise every one who has anything to do with trade-unionism to get this work and not merely read it but study it as you would study a book on electric motors to find the difference between an induction motor and a synchronous motor, between one that was simply wound and one that was compound wound.

You will find that trade-unionism can be classified under two broad general heads, one based on structural varieties, and one on functional varieties. As Professor Hoxie points out, there are four divisions under each head and any one of the structural varieties may function in any one of four different ways. You will learn that while, to you, decreased output on the part of the laborer seems inexcusable, yet, for him, it has an intense and immediate value. You will find the reason why he insists that the good and the poor workman shall each turn out the same amount every day, and you will find that he has most excellent reasons for this, reasons that probably never entered your head. You will learn why the locomotive engineers of the United States can have one strong central national union, and why this is impossible with the men who dig ditches. You will discover why the Knights of Labor movement failed and why the American Federation of Labor has succeeded. There is one basic and most important factor which you must realize, namely, that, talk as you may, the interest of the laborer and the interest of the employer are diametrically opposed, just as the interest of the buyer and the interest of the seller are opposed, that from the very nature of things they can never be identical, and that the best that can ever be reached is a compromise. And who is better qualified to bring about this compromise than the well

trained engineering manager who, with his broad knowledge and experience with both capitalist and laborer, is enabled to act as an arbiter or a judge and arrive at a decision at least fairly equitable.

It is the engineers of this country who are in a position to solve the labor problem, or at least to produce a solution as nearly ideal as possible. It is you who are to convince the employer that, in the long run, he is going to be better off by increasing the wages of his men, reducing their hours of work, and improving their living conditions. It is you who must convince the laborer that it is to his interest to work as efficiently as he can and to produce as large an output as is possible. You will have to do this by education. It is difficult to convince a laborer that by increasing his efficiency and his output he helps himself, because he only looks to immediate results. But do not be carried away with the idea that because the laboring man upholds an economic fallacy you cannot convince him of his error.

About ten years ago I started to develop a low-grade copper mine in Arizona. As mine superintendent I had N. Oliver Lawton, a member of this Institute, whose experience at Lake Superior has made him familiar with what is known as the one-man air-drill. This is a light machine weighing about 125 lb., which can be readily set up and operated by one man. We started to use these in Arizona where, before, nothing but the larger and heavier machine, requiring two men, was in use. There was an immediate opposition from the men and we were accused of trying to throw half the normal number of miners out of work. Whenever I went through the mine I took the opportunity to tell the men that this orebody, up to that time, had not been considered 'ore', that it was 'rock', and that nobody thought it was worth exploiting; that, far from throwing one man out of work, we were giving two men jobs, that if two men had to work on a drill the cost of mining would be so high that the material would not be ore, but that if we gave each man a drill and put him to work in a separate drift, then the rock would become ore, that these men would have employment and that a new industry would be started. About three months of this propaganda convinced the men of the truth of our claim, and in a short time it would have been impossible to get the men to go back to the old two-man drill because each man now felt that he stood on his own feet and got credit for the whole distance he drifted. This is only one example, but it indicates what can be done by education. The old-time manager or old-time superintendent would simply have said, take the job or leave it; but this is not the attitude for the modern engineer.

The assertion is made in Washington that it is difficult to get executives for war work, particularly executives who understand the handling of man-power. I am told that some of the new plants for war industries have been most carefully laid out, taking into consideration the routes by which material is to arrive at the plant, its progress through the works, and its method of removal, the supply of water, coal, and other material, but in a great many cases no thought has been given to the han-

dling of the men, to their housing, or, if they are to be brought from an adjacent town, of the method of transporting them to and from the plant. These have been left to a hit or miss adjustment after the plant was up.

For several years the industrial department of the Y. M. C. A. has had a secretary who has devoted himself almost entirely to impressing upon the engineering schools the necessity for having a course in human engineering, and in 1916, under their auspices, the first convention to discuss the human side of engineering was held in Ohio. They lay great stress upon the advantages which would accrue to engineering students if they had an insight into the mental operations of the laboring man, and this has been fostered by getting the engineering students to volunteer one or more hours of the week for instruction to laborers employed in adjacent plants. This instruction is either in the English language, in citizenship, or in athletics. A man who has volunteered for this work for a year or more, on going out into active life is a much more capable foreman than one who graduates from an engineering school and meets his first laborer somewhere on his new job.

Lately the National Americanization Committee of New York, of which Frank Trumbull, of the Chesapeake & Ohio Railroad, is chairman, has been conducting similar propaganda, sending to the various educational institutions of the country a proposed basis of a course on industrial engineering. The committee realized the importance of this in preparing engineering graduates for the problem of properly utilizing the man-power of the country. This proposed course goes into the scope of industrial engineering, describes the problem and the field; it takes up the question of the engineering insight of the work in reference to plant-building, its location, and the fundamental considerations in its construction; it takes up the management and division of the work, the analysis of the costs, and the machinery, and the materials, and the efficiency methods. It goes into the question of employment, management, and the methods for hiring, promoting, and transferring men. It also takes up industrial welfare with the various incentives to the workman and the provisions for his health and recreation, and for the vocational training of either himself or his children. It also gives instruction in that branch which is so often neglected, and that is conditions outside of the plant, the housing of the men, the planning of the town, and the health and recreation and education of their families. It takes up the problem of Americanization and what shall be done to make our melting-pot efficient, without dross, and finally it gives him instruction as to what has been done and what should be done in legislation.

You engineers who are college graduates should use your influence to see that courses in human engineering are introduced in your Alma Maters, if they are not already there. Do you mining engineers realize that your training and your experience, touching as it does on all branches of engineering, fits you better for broad and important work than those in almost any other profession? How many of you have been under the necessity

of developing a large mining property in some out of the way place, when everything came before you and nothing could be left to chance, where you had to see that your own town was built and provided with waterworks and sewers, lighting-plant, and schools? You had to develop a property in a place where nothing existed and you did not have a well-organized community to fall back upon with all these adjuncts provided. Only recently one of my former superintendents came into the office to tell me that he had given up a \$12,000 per year position to take one with the Government for \$3600. He did not hunt this Government job, it came after him. They asked him to go on to Washington and take a job in the Ordnance Department. They said that they had found that a mining engineer has had such varied experience, and has driven so little in ruts, that at a minute's notice he can jump from 6-in. projectiles to baled hay.

The Chrome Industry

According to a statement by the U. S. Shipping Board, the Government is restricting importations of chromite from other countries than North, South, and Central America and the West Indies, in order to set free additional ships for the supreme military effort of the United States. There are, at the present time, considerable stocks of New Caledonian ore on hand and in transit, and, besides the domestic and Canadian supplies, new sources have recently been opened in Brazil and Cuba. Brazil is counted upon to produce 25,000 tons of ore in 1918, and a considerable tonnage is expected from one mine in Cuba which already has been partly developed and will be put into operation at once.

Estimates differ as to the amount of ore which can be produced in California and Washington, which are our principal sources of domestic supply; but every effort will be made by the Government to stimulate and encourage this production. In addition to this, however, much would depend upon the attitude of those concerned in the chrome industry, and upon the methods used by producers and consumers alike. It appears that the chrome industry in California is not organized, and that an immense amount of annoyance and detriment has been caused by middlemen who do not represent responsible operators and who come between the producer and the consumer in such a way as to discourage mining in many cases. In an attempt to correct this evil, the Electro-Metallurgical Co., the chief purchaser of chrome ores, has inserted an advertisement in many local Californian papers, stating their minimum ore prices on a basis of \$1.25 per unit for 38% ore. Organized action by the Pacific Coast chrome industry would doubtless be effective in this and other matters. The War Industries Board and other departments in Washington, it is understood, will co-operate in stimulating production. This co-operation must also be extended by the Railroad Administration, and the discouraging effect of railroad embargoes must be removed if the shipping program is to be carried out. Several plants are being built on the

Pacific Coast to manufacture ferro-chrome, but their chief difficulty has been in obtaining electrodes. It is to be hoped that this lack will soon be overcome in some way.

Concentration of low-grade ores must be undertaken if the expected requirements are to be met. With the increased prices for chromium, it is possible that the old Pennsylvania-Maryland chrome district may be able to produce some ore which can be concentrated to a workable product.

On the part of the consumers, great economies can be effected in the use of chromite, and are already being carried into effect. For example, about 40,000 tons of ore has been used annually for refractory linings in copper and steel-furnaces; but it has been ascertained recently, beyond any doubt, that 90% of this chromite can be substituted by magnesite, of which large supplies are available in Canada and Washington. As a matter of fact, these economies in the substitution of magnesite for chromite linings already have gone into effect to a large extent. Manufacturers are urged to practice this economy more extensively. The U. S. Bureau of Mines estimates that the maximum allotment of 12,000 to 15,000 tons for refractory purposes for 1918 will be ample, and from information obtained through manufacturers it would seem that this estimate is liberal and even may be diminished. Manufacturers of ferro-chrome may be obliged to use lower-grade ores than those to which they have been accustomed. This appears to be feasible from a metallurgical standpoint, as it will be simply a matter of adjustment of practice. Steel-makers can get along with a lower grade of ferro-chrome if it becomes necessary.

MOLYBDENUM ORE treated in 1917 at the concentrators of the International Molybdenum Co. at Renfrew, Renfrew Molybdenum Mines at Mount St. Patrick, and the Mines Department at Ottawa, Canada, amounted to 692 tons. From this ore 80,614 lb. of concentrate was produced, worth \$108,501. The molybdenum contents of the concentrates varied from 52.9 to 93.5% MoS₂. From the plants of the International Molybdenum Co. at Orillia and the Tivani Electric Steel Co. at Belleville there was a production in 1917 of 149,000 lb. of ferro-molybdenum valued at \$348,775.

GOLD production of India is fairly steady at approximately 600,000 oz. per annum. This metal (917 fine), prior to the War, was sent to England for refining, but it is now proposed to do this and coin sovereigns at Bombay. This is the nearest large city to the Kolar gold-field, State of Mysore, which contributes 90% of the total gold output.

ARSENIC is increasingly needed as an aid for protecting our food supply through its use as an insecticide and for killing weeds. The domestic output for 1917 was 6151 tons, representing 60% of the total consumption. The War Minerals Bill is hoped to stimulate production in this country.

Concentrates

RAWHIDE PINIONS economically and efficiently replaced those of brass and steel at the Braden mill in Chile.

IN DRILL-BITS, the distribution of work throughout the entire length of the cutting edge is essential for efficient drilling, which depends on skill in sharpening.

THE GREAT ENGINEERING FEATS of China are the Grand canal, the Hangchow bore, the Wall, the salt wells of Szechwan, and the irrigation system of Kwanhsien.

POWDER COSTS at the Homestake mine, South Dakota, in 1917, when 1,677,623 tons of ore was extracted and 19,320 ft. of development done, amounted to 17 cents per ton treated.

A QUINTAL weighs 100 Spanish pounds, in Chile equal to 46 kilogrammes, where it is used in reporting nitrate business. The Spanish pound weighs 460 grammes, or 1.0141 lb. avoirdupois.

CEMENT AND SAND—3 to 1 mixture—sprayed on mine timbers, by compressed air, renders them fire-resisting to a considerable degree. Any desired thickness may be built up by spraying in layers, by the cement gun.

A SMELTING-FURNACE is not a melting-furnace, from a metallurgical standpoint. In the former, ore and fluxes are reduced to matte or metal; in the latter, some metal is simply melted for casting into any desired shape.

CHOKED ROLLS and full ball-mills result in high torque in electric motors. At the Braden mill in Chile, where squirrel-cage induction motors form part of the power-plant, to start those ranging from 15 to 300 hp. directly on line voltage, it was found necessary to re-connect the auto-starters.

PITTING in steam-boiler plates may be filled by welding in metal by means of an oxy-acetylene jet. Some insurance companies will not pass such boilers, nor some State accident commissions. On curved plates this method is not advisable, but on flat sheets the risk of failure is less.

SADDLE-REEFS or veins of the Bendigo type, Victoria, are also worked at Westonia, Western Australia. In the Edna May mine the saddles follow each other in a horizontal series instead of vertically, as at Bendigo. One leg of the saddle turns on the greenstone foot-wall, the other striking across the gneiss.

THE PRINCIPAL ADVANTAGES of the electric furnace over other methods of making steel are: (1) It economically produces the highest temperature obtainable. (2) It offers a ready and easy means of exact temperature control. (3) Any temperature or treatment by slags is possible without contamination of the charge through gases and other impurities. (4) Fusion is effected in a perfectly neutral atmosphere. (5) More rapid steel melting

can be accomplished with the electric furnace than with any other types available, according to T. R. Hay in 'The Iron Age.'

CHARCOAL precipitation of gold from cyanide solutions will probably come into extensive use in Australia, where zinc is difficult to secure, and is very costly. At the Yuannui mine, Western Australia, H. R. Edmonds finds that, on a working scale, there is an advantage of 70% in cost by using charcoal compared with zinc-dust. The bullion is also of higher fineness.

COMPRESSED-AIR hoists, pumps, and drills are fast displacing steam-power in the Missouri-Kansas-Oklahoma zinc-lead region. As far as economy is concerned it has been demonstrated that with direct-connected gas-driven air-compressors the entire shaft-sinking equipment can be operated much more cheaply by air than with steam. The only reason that compressed air is not generally used is because proper precautions are not exercised to prevent engines and pumps freezing at the exhaust.

MANY SPECIES OF EUCALYPTUS TREES in Australia have a distinctive selection in habitat. Some prefer a siliceous soil, others a basic soil, while many approach a common boundary, yet do not intermingle. In four related species the relative constancy of manganese in the ash is striking, amounting to 1 part in 1,000,000 parts of anhydrous timber. In five other species the manganese is 1 part in 60,000 parts of anhydrous timber. In the ash of the 'box' species—*eucalyptus albens*—the lime content is over 50%, and magnesia only 2%. Oil from the broad-leaf peppermint—*eucalyptus dives*—is the best of all essential oils for use in flotation. The yield from this tree is 3% of oil. The cheaper phellandrene *eucalyptus* oils act better in flotation than the more expensive oils from these trees.

SODIUM MANGANATE is now used on the Rand as a substitute for all purposes where refined potassium permanganate was used. The substitute is made locally by mixing 1 part by weight of 40% manganese ore to 1.44 parts of caustic soda; also 1 part of ore to 1.1 parts caustic soda, and 0.4 part nitre. The ore is ground so that 61.6% passes 200-mesh, with only 5.7% remaining on 60-mesh. The ore and soda are well mixed in 500-lb. charges, each being placed on the hearth of a four-deck muffle-furnace. No rabbling is necessary. The temperature is kept at 650 to 750°C. for two or three hours, yielding a product containing from 18.2 to 21.9% sodium manganate; but with an initial temperature of 450°C., gradually raised to 560°C. and held there for 8 hours, and cooled for 4 hours, a 28% product is made. The compound should be placed in sealed containers to prevent decomposition. The loss in weight during heating is 12.5%. The reactions are:

Without nitre

and with nitre

Ore-Reserves of the Disseminated-Copper Mines

The reports of these companies for 1917 give the following estimates:

Mine	Tons	Copper, %
Chino Copper	95,555,843	1.656
Inspiration Con.	87,864,378	1.388
Miami Copper	48,760,000	1.581
Nevada Con.	70,025,322	1.580
Ray Con.	89,812,522	2.048
Ray Hercules*	9,500,000	1.770
Utah Copper	371,752,000	1.390

*Ray Hercules is a new mine, about to start milling.

The Disseminated Copper Mines in 1917

Essential results of the six great disseminated-copper mines of the United States are shown in the following table, which covers the past two years:

Mine	Tons milled		Copper, %	
	1917	1916	1917	1916
Chino	3,608,100	3,094,400	1.640	1.830
Inspiration Con.	3,891,075*	5,332,058	1.338	1.548
Miami	1,640,206*	1,842,017	2.032	2.070
Nevada Con.	4,064,095	3,922,634	1.462	1.632
Ray Con.	3,560,900	3,332,340	1.635	1.607
Utah Copper	12,542,000	10,994,000	1.337	1.435

*Operations curtailed by labor troubles.

Inspiration Mill Statistics, 1917

During 1917 the concentrator operated full time until July. From then until late in August it was out of commission, due to labor troubles. Full capacity was not reached again until March 1918.

Ore milled, dry tons	3,891,075.000
Per day of milling, tons	12,884.400
Average number of sections at work	13.756
Average rate per section, tons	936.700
Assay of mill-feed, copper, per cent	1.388
Screen analysis of feed to concentrating machines (on 48-mesh)	3.300
Copper oxide in mill-feed, per cent	0.279
Assay of general mill-tailing, per cent	0.355
Copper oxide in mill-tailing, per cent	0.237
Copper in concentrate produced (smelter assay), per cent	29.270
Copper in flotation concentrate, per cent	35.570
Copper in table concentrate, per cent	13.930
Moisture in general concentrate, per cent	17.200
Concentrate produced per ton of ore dressed, tons	0.036
Recovery of copper in milling calculated from assay only, per cent	75.340
Assays and weights of concentrate and ore, per cent	75.780
Assays and weights of concentrate and tailing, per cent	75.460
Assays and weights of ore and tailings, per cent	75.360
Recovery of copper sulphide in ore, per cent	89.730
Gallons	348
Water used per ton of ore	
Water consumption for first six months of year per ton ore milled:	
Reclaimed in tanks at foot of mill	356

Reclaimed in tailing-ponds	475
New water from Kiser pump-station	277

Total 1,108

Power used per ton of ore milled for first six months of year, in kilowatt-hours:

Coarse crushing	0.43
Fine grinding and concentrating	10.87
Blowers for flotation air	2.42
Filter and reclaiming water	2.01
Lights	0.07

Total 15.80

Pounds

Steel-ball consumption in fine grinding, per ton of ore milled (for year) 1.82

Flotation oils per ton of ore milled:

Coal-tar	1.21
Sundry oils	0.11

Total 1.32

A 200-ft. diameter concrete settling tank for tailing was constructed, and the filter plant was enlarged 50%.

Mill recovery, %		Cost per lb., cents		Price received, cents	
1917	1916	1917	1916	1917	1916
69.32	66.59	11.390	8.710	25.810	26.465

74.53	72.20	12.649	10.577	25.900	26.724
61.10	62.34	10.995	6.950	24.186	26.139

Concentrating Zinc Ores at Butte

During 1917 the Butte & Superior Mining Co.'s mill was considerably improved, especially in the flotation department and tailing disposal arrangements. Although there was a period of re-adjustment, and a complete shut-down for six weeks on account of labor troubles, the mill recovery only dropped from 93.13 to 91.13% of the zinc content of the ore. The plant dressed 461,953 tons having the following assay and total metal contents:

Assay	Zinc, %	Lead, %	Copper, %	Silver, oz.	Gold, oz.
	15.4692	1.0913	0.1717	5.8003	0.00908
Contents	Zinc, lb.	Lead, lb.	Copper, lb.	Silver, oz.	Gold, oz.
	142,920.807	10,082.584	1,586.302	2,679.462	4196

The concentrating plant yielded 138,661 tons of zinc and 2543 tons of lead concentrates. These assayed as under:

Zinc concentrate:		Copper, %	Silver, oz.	Gold, oz.
Zinc, %	Lead, %			
47.3636	3.3498	0.4705	17.8348	0.0277
Lead concentrate:		Copper, %	Silver, oz.	Gold, oz.
Zinc, %	Lead, %			
35.5600	13.7540	0.2917	21.3620	0.0296

The metal contents of all concentrates was 132,036,735 lb. of zinc, 11,098,051 lb. of lead, 1,329,570 lb. of copper, 2,527,302 oz. of silver, and 3918 oz. of gold.

The direct cost of milling was \$2.52 per ton of ore, an increase of 36%, due to abnormal conditions.

MACHINE-SHOPS on Rand mines have £718,090 (\$3,450,000) invested in them. They employ 9366 people, who were paid £1,318,972 (\$6,330,000) during 1916, and produced work valued at £2,654,147 (\$12,740,000).

REVIEW OF MINING

BUTTE, MONTANA

Resume of Manganese Possibilities at Butte.

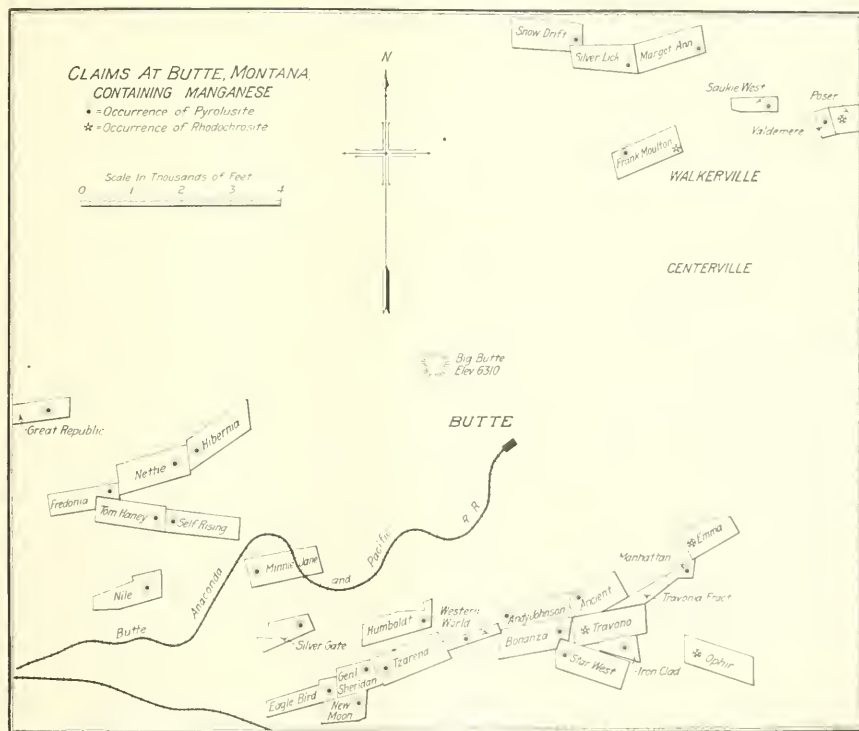

'Manganese at Butte, Montana,' is the title of Bulletin 690-E, by J. T. Pardee of the U. S. Geological Survey. The manganiferous gangue of the silver-zinc lodes, formerly regarded as waste, is under present prices a possible source of considerable manganese. The smaller part of this material consists of manganese oxides in outcrops and upper portions of the lodes. Reserves of these are as follows:

Tons	Mn, %	SiO ₂ , %
26,000	40.0	10
132,000	24.0	50
270,000	11.5	73

It is possible that the second class can be concentrated. Most of the manganiferous material below the oxidized zone consists of rhodochrosite and rhodonite—the carbonate and silicate of manganese, respectively. The former mineral is fairly pure, that in the Emma mine carrying from 34 to 41% Mn and as low as 1% SiO₂. A light roast drives off

carbon di-oxide, and increases the manganese content. Several thousand tons are available, and large additional quantities should be developed. The amount of 15% is estimated at several million tons. About half of the manganiferous zone at Butte lies north of the copper area and east of the rhyolite, the remainder in the south-west and west sections. The mineral is most abundant in the south-west part. Two main types of veins are found at Butte—the black or oxide ore of the outcrops and oxidized zone, and the pink or carbonate and silicate below. Most of the manganiferous lodes carry less than 40% Mn, and are high in silica, with 3 to 4% iron. Whether Butte can be counted upon to produce large quantities of manganese at an early date depends rather on ore-dressing problems than on mining.

Advice from Boston states that the United States Manganese Corporation has been chartered in Delaware with capital of 100,000 shares, 8% preferred, and 600,000 shares common, par value of both \$10. The new company has acquired control of all manganese deposits at Butte and vicinity and practically all independent manganese concentration plants in Montana.

MANGANESE-BEARING CLAIMS AT BUTTE. (MAP RE-DRAWN FROM ORIGINAL PREPARED BY THE ANACONDA COMPANY.)

PLATTEVILLE, WISCONSIN

Zinc, Lead, and Pyrite Situation in May.

Zinc mines experienced numerous and distressing drawbacks during the first half of May. For a time it appeared that many companies would be compelled to suspend entirely until better conditions prevailed. Prices for ore dropped seriously and labor was short through young miners being drafted. Ore quotations dropped from \$61 base to \$50, with the range on second grades at one time as low as \$40 per ton. On the lower grades required for the separators, usually averaging 30% zinc, prices fell as low as \$16 to \$18, a figure that producers declared was below cost of production. This branch of zinc mining suffered appreciably on this account, and many mines were shut-down with bins well filled with unsold concentrate until about mid-month. The surplus zinc ore in the field was conservatively estimated at 10,000 tons. The appointment of an allocation committee at Washington early in May began to bear fruit soon after, when the price for 60% ore was brought up to \$75 per ton for all blende entering into rolled sheet metal. While this figure applied on a small quantity of high-grade offered for sale, it nevertheless inspired mining men with hope that other ore would receive better prices.

Production in the field shows a decided curtailment, about 60% of normal, while shipments to smelters also reveal lower tonnages. Mine development has been brought to halt at all points, also erection of mine equipment. Several independent mining corporations have been negotiating with stronger companies for a complete sale and transfer of their properties. They argue that high costs and low prices for ore are bound to continue indefinitely, and it is best to get out. In fact, it will cause no surprise to find that within the next six months mining in Wisconsin will be under control of the larger operating groups affiliated with or backed by the leading smelter interests, which they now supply with ore.

Lead-ore producers have not fared as well this month as was hoped, and sales were restricted to 3 cars each week for the first two weeks. Prices dropped from \$85 for 80% ore to \$80 per ton, with fluctuations in value raised or lowered \$1 per unit. Sales scarcely covered current output, so that the reserve in the field figured at more than 2000 tons at the beginning of the month was not diminished. However, this was also little increased under the lower offerings, the lower prices for zinc ore resulting in a decreased output of this ore, which in turn is mainly responsible for recoveries of lead ore, the latter being mostly a by-product in wet concentration of zinc ore. New buying interests entered the field about mid-month but it was apparent buyers were after lead ore on consideration that current bids were acceptable, and where not to let the ore alone. Prices however were improved soon after this, the range being from \$80 to \$84; sales at the latter figure being made for delivery in the week of May 18.

Exceptional developments transpired in the production, sale, and shipment of iron pyrite, mainly used in the manufacture of sulphuric acid. Prices show no change, but as most of this grade of ore has been sold under contract no figures are available. The current weekly recoveries for the field, exclusively fine material obtained at separating plants in treating zinc concentrate, amounts to 800 tons. Shipments have been increased to 2500 tons in a single week, and for this month total more than 5000 tons, proving that considerable reserve ore has been worked off. The building of new acid plants in the field should stimulate output of pyritic ore, in the crude state, which acid-makers declare is better adapted to their requirements than the fines obtained at separating plants by magnetic-ore separation. The bulk of the pyrite sold so far this month has been going to the Grasselli Chemical Co., at Cleveland, Ohio.

VICTORIA, BRITISH COLUMBIA

Manganese, Molybdenite, and Tungsten.—The French Complex Ore Process.—Iron Ore.

Manganese is one of the minerals much in demand at present. British Columbia has some manganese, and one deposit near Kaslo is sufficiently promising to have induced American capitalists, reported to have their headquarters at Seattle, Washington, to acquire the rights of development from the owner, A. J. Curle. New equipment is being erected, and it is expected that production will commence this year. The output is intended for the United States, it being possible now to ship manganese out of Canada without restriction. This condition has been brought about, within the past few months, through the representations of Mr. Curle, supported by the Minister of Mines for the Province. The stand taken by the latter was that, while it was just and right that such Canadian resources should be available first to the British Empire for the manufacture of munitions and other war essentials, it should be possible for the owners of property, when the Imperial Munitions Board indicated that it did not require the ore, to ship either to the United States or any other of the Empire's allies. The reasonableness of this was recognized and consequently the embargo, which had existed ever since war broke out, was removed as far as the United States and France are concerned.

It may be said here that the same is true of molybdenite, against which was an export embargo. This no longer exists. There are known to be considerable bodies of this mineral in British Columbia, notably that on Alice arm, on the northern coast. This has not been exploited heretofore because of an unfortunate tangle over the title to the property, but it is likely that this difficulty soon will be overcome.

Tungsten, another of the ores from which the former embargo has been lifted, is found in this Province. There is one scheelite deposit in the Cariboo district, as yet undeveloped, but samples are of promising quality.

Legislation had been introduced to the British Columbia Legislature, the annual session of which recently adjourned, giving the Government power to guarantee the bonds of the French Complex Ore Reduction Co., Ltd., to the extent of another \$25,000. The Province already has endorsed this company's issues up to \$40,000. With this capital a plant has been erected at Fairview, B. C., near Nelson. It has been equipped specially for the handling of the peculiarly refractory zinc-lead ore of the Slocan district by the French electrolytic process. The cost of plant, however, so exhausted the company's finances that it was unable to enter into the custom business on such a scale as to defray overhead expenses and keep ahead, and it became necessary to close down. The position was aggravated by the fact that with the great rise in price of zinc and lead the Consolidated Mining & Smelting Co., the largest smelting concern in western Canada, was able to install an electrolytic plant at Trail and to reduce the silver, lead, and zinc ores of the district. Under these circumstances the French Complex Ore Reduction Co. was compelled to cease operation, but its management is looking forward to the time, which in its opinion seems to have practically arrived now, when the Consolidated company will be unable to pay the prices it has been giving, and when the French cheaper process will be able to prove itself. It is claimed for this process that it is capable of recovering from 90% up of the zinc content of these ores, and that it can be run at a profit when the quotation on zinc falls to 5c. per lb. or thereabout. The Government, having placed its credit behind the company in the first instance, has indicated, by the legislation referred to and which no doubt will be passed, that it is prepared to give the company and its process every chance to make good.

Since the above was written, authority was given by the

Legislature to advance the French company another \$25,000.

In order to facilitate the important work of obtaining more knowledge of British Columbia's iron-ore resources, the Minister of Mines at the last session of the British Columbia Legislature obtained an amendment to that section of the Mineral Survey and Development Act, 1917, dealing with the drilling of mining properties. This Act gives the Minister power in diamond-drilling a claim or prospect, to place a charge against such property of the cost of the work, "together with a bonus equal to the total amount of the cost and interest at 6% per annum, computed annually." The amendment sets out that "in the case of iron mines, that is to say mines in which the iron recoverable from the ore is such that they are classed as iron mines by a resident engineer, no bonus shall be charged, and the amount payable to the Minister of Mines shall be the cost of the drilling or boring, with interest as aforesaid."

WESTCLIFFE, COLORADO

Mining Operations in Custer County..

Querida.—The Bassick mine has been taken over by the Bassick Mining & Reduction Co., under a long term lease, a company organized for the purpose by Harry S. Thayer

MINING DISTRICTS IN CUSTER COUNTY, COLORADO

of Boulder. A 100-ton flotation mill will be built at once to treat ore from both the mine and dumps. New hoisting machinery using crude oil for power will be substituted for the old steam plant. The Bassick mine was discovered in 1877, working continuously from that time until 1904 when the concentrator was burned. It produced many millions of dollars worth of gold and silver. Little has been done with it during the last 14 years on account of quarrels among the owners. The ore occurs as layers of metallic sulphides around the boulders in an andesitic agglomerate, which fills an old volcanic crater.

Rosita.—The Rosita Mining & Milling Co., under the management of Joseph Bradley, has taken over the Vernon, Leavenworth, Pioneer, Victoria, and Cymbeline claims. Work is being done at present through the Leavenworth tunnel, where a small but high-grade silver streak is being mined.

Hillside.—The Peerless copper mine has recently had an air-compressor put in; development is under way.

Westcliffe.—There is a great deal of activity in the White Hills district. The Passiflora Mining & Milling Co. is sink-

ing its Herman shaft to the 330-ft. level. On account of the small capacity of the air-compressor this has necessitated a reduction in the amount of ore stoped and has curtailed shipments. There are half a dozen sets of lessees working on small blocks owned by this company, nearly all of whom are shipping regularly. —A 100-ton cyanide mill is being built on the King of the Carbonates to treat a large quantity of low-grade ore which has been developed on the property. —The Silver Bar mill is to be started soon on ore from the Quartz King and other claims. —George Shaeffer is making regular shipments from the Lady Franklin. —Preston & Beaman are operating the Black Friday, shipping a little high-grade ore. —The Bull Domingo Mining Co. has leased the old Bull Domingo mill, which now belongs to the Passiflora company, and is putting it in shape to concentrate Bull Domingo ore. —Development is being done on several of the copper claims in the Sangre de Cristo range south-west of town, including the Princess Annie and the Hermit Lake.

SUTTER CREEK, CALIFORNIA

Wage Increase.—Conditions at the Central Eureka.

As many men were leaving the county to get the better wages paid at copper and other mines, making the local mines short-handed, operators in Amador have raised wages of all underground employees 50c. per day, and in the majority of cases a 25c. increase to surface men, effective May 1. Miners, machine-men, and timber-men now receive \$4, and car-men and shovelers \$3.50 per day. At some of the mines where sinking is by contract, the men earn more, but the increased rate is already having an effect on the labor situation, men returning from centres where conditions are less favorable than here.

Sinking at the Central Eureka was suspended early in May, when the shaft had reached a point 135 ft. below the 3425-ft. level. For prospecting, a short cross-cut was then driven into the foot-wall from the sump, and ore was found of value enough to convince the management that the same character of rock exists at this depth as was worked so successfully on the 3350-ft. level, and slightly developed at 3425 ft. A station to be known as the 3500 ft. is now being cut above where this sump cross-cut was run, and while men are engaged in completing this and a shaft chute, others are cross-cutting from the station to open this orebody. Little work was done at 3425 ft. other than to determine the occurrence of pay-ore near the shaft, and no permanent station was cut, it being deemed more economical to work the ground between the 3350 and 3500-ft. levels from the new 3500-ft. workings. The recurrence of the vein in the bottom of the mine gives reason to expect good returns for money put into this property, notwithstanding the fact that the closing down of the neighboring South Eureka mine has saddled all the pumping expenses for the two properties on the Central Eureka. The latter has assumed charge of the pumps and hoisting equipment at the South Eureka, the main pumps for the two mines being in that shaft. The burning out of a motor underground, together with necessary pump repairs, is necessitating the handling of water at the South Eureka by means of skips for a short time, but the plant is being rapidly put into more satisfactory condition. Twenty of the forty stamps at the Central Eureka have been dropping during shaft-sinking and recent development, but on account of labor shortage it may be difficult for some time to keep the mill fully supplied with ore. Prospects are good for the extraction of a fair quantity of pay-ore at minimum expense, though short handed, as the levels are being closely studied and worked systematically with this object in view. Since the resignation of Fred Jost, Albion Howe of San Francisco has been appointed superintendent, with Henry Warrington, assistant, and William J. Bryant, mine foreman. George P. Harper of Martell has superseded A. W. Witte as mill foreman.

THE MINING SUMMARY

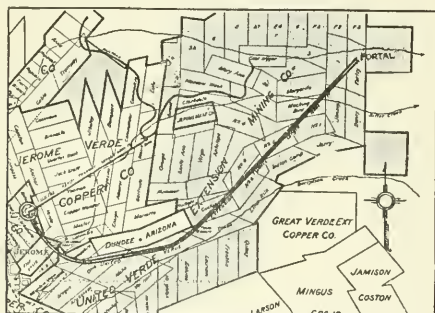

ALASKA

Juneau.—Alaska Gold Mines reports for the first quarter of 1918 that 469,695 tons of 98-cent ore was treated, of which 78.99% was recovered. Operations cost \$0.7c. per ton, leaving a profit of 1.71c. per ton. The quarter resulted in a total loss of \$8018. Labor was short, causing a decrease in tonnage of 680 per day when compared with the last quarter of 1917. In the December quarter there was a profit of \$37,684.

ARIZONA

Ajo.—The New Cornelia company's main shaft is down 190 ft. It is to be sunk 250 ft. before driving south to the sulphide orebody is started. A new hoist has been erected. This is the first underground work on any scale that has been done in the district. Daily shipments of sulphide ore to the C. & A. smelter at Douglas are about 200 tons.

Jerome.—The United Verde Extension will take 9 months to complete its tunnel. The Potter Construction Co., which

PART OF JEROME DISTRICT, ARIZONA, SHOWING DIRECTION OF UNITED VERDE EXTENSION TUNNEL

had the contract for driving this opening, has been re-organized as Potter, Jarvis & O'Rourke. The work was described in this journal of April 27.

Water in the Dundee-Arizona is 30 ft. below the 450-ft. station, probably due to work in the Texas shaft section of the United Verde Extension tunnel.

On the 600-ft. level of Calumet & Jerome about 4500 ft. of lateral work has been done. Ground recently opened is of a promising character. The south cross-cut is in 1800 ft. from the shaft.

The Grand Island diamond-drill is down 908 ft., without cutting the lode exposed on 208-ft. level. Another hole will be driven. After passing the 700-ft. mark the bore passed through 30 ft. of jasper before entering a well-mineralized schist-zone.

Pittsburg-Jerome is driving two places on the 500-ft. and five on the 900-ft. level.

The Barter adit of Verde Squaw has opened good-looking ore.

Diamond-drilling on the 1045-ft. level of the Columbia shaft workings at the Jerome is disclosing some favorable formation.

Verde Combination shaft is down below 930 ft. in a soft blue schist carrying iron pyrite and chalcocopyrite.

Oatman.—The Gold Ore has completed its first 30-day run at the Gold Road mill, having treated 1200 tons. Ore from the 700-ft. level is now being milled.

United Eastern in April produced 8000 tons of ore yielding \$184,000.

The Oatman United shaft has reached the 400-ft. level, and driving east and west has been started.

Prescott.—The Ford Gold & Silver Mining Co. has been formed to take over and work the Promoter gold claims in the Crook Canyon district. The dump-ore is to be milled at once.

Ray.—Report of Ray Consolidated for the first quarter of 1918, compared with that of the last quarter of 1917, is as under:

	1st quarter 1918	4th quarter 1917
Ore milled, tons.....	\$78,200	\$93,800
Copper content, per cent.....	1.587	1.600
Recovery, per cent.....	73.60	73.74
Copper (including direct smelt- ing), pounds.....	22,011,525	22,750,677
Cost of mining, per ton.....	\$1.46	\$1.24
Cost of milling, per ton.....	0.98	0.91
Cost of copper, cents per pound.	15.307	13.836
Profit.....	\$1,105,863	\$2,570,872
Dividends paid.....	1,577,179	1,577,179
Deficit or surplus.....	- 471,316	+ 993,693

CALIFORNIA

Cloverdale.—In the 'Press' of May 18 it was stated that the Western Minerals Co. was operating the Cloverdale mine, and that the ore averaged 10% quicksilver. This is incorrect, as it is the Western Mercury Co., and the grade is 0.5%.

Heroult.—Noble Electric Steel Co. has two furnaces making ferro-manganese at the rate of 500 tons per month.

Trinity Center.—The 40-stamp mill and 225-ton cyanide-plant at the Headlight mine are being dismantled. The mine has stood idle since October 1915, when it was found impossible longer to treat ore profitably by any known method, owing to the heavy sulphides in it. The mine belongs to the Trinity Gold Mining & Reduction Co. Ore worth \$500,000, is said to be developed. The plant was run 18 months, from 90 to 100 men being employed.

Ildria.—The New Ildria Quicksilver Co. reports as follows for 1917:

The output of mercury was 11,000 flasks, an increase of 172. Shortage of labor hampered operations, while supplies increased 100% in cost. Another aerial tram, 3500 ft. long, to carry ore from No. 5 Ildria level to the furnaces, was completed. The plant was improved considerably. The grade of ore was a little higher. Demand for quicksilver was good. Accounts are not clearly stated, but the 'gross income' of \$410,774 was reduced to \$146,771 after charging depletion and depreciation, also reserve for Federal taxes. Current assets total \$477,675, and liabilities \$298,705.

COLORADO

Blackhawk.—The Pittsburg mine is to be re-opened soon in charge of William Auger. Pumping has been continued during suspension of work. The Gilpin-Eureka mine here and the Gold Lode in the Russell district are yielding good gold ore.

Cripple Creek.—Diamond-drilling on the seventh level of the Cresson mine has shown 2 ft. of \$92 ore, and farther on 12 ft. of \$12 ore, according to the monthly report of Louis S. Noble, consulting engineer. Hole No. 36, driven to prove the discovery, showed 8 ft. of \$101 ore about 10 ft. distant from the good-grade streak and also 5 ft. of \$27 ore in another section.

The Vindicator flotation mill in this district treated 20,114 tons of \$2.04 ore at a milling cost of 49c. per ton and net profit of 25c. per ton during April. The process is a combination of washing and flotation.

Eureka.—The Sunnyside company has been testing small units in the new flotation mill during the past few weeks. The plant will produce a large quantity of zinc concentrate during the season of 1918.

The D. L. & W. Mining & Reduction Co. has not commenced shipments yet, but soon will.

La Plata.—Mining in the La Plata is practically at a standstill. Small shipments have been made from the Idaho, Tippicanoe, and the Mountain Meadow mines.

Ouray.—The Hidden Treasure mine will be developed by E. P. Bauer. A few men are at work cleaning out tunnels. A large amount of ore is ready for shipment.

The Rare Metals Mining Co. has made application for a patent on the Black Dragon lode.

The Senorita has a car of ore ready to ship.

Gannon & Hall, new lessees on the Rose lode, have shipped their second car of ore.

There will be five mills in the Ironton mining district during the coming season. While present production is low, prospects for a busy year are encouraging. With the high price for silver, mines here can ship at a profit. Among the most important factors influencing local development is incorporation of the Ouray Consolidated Mining & Reduction Co., the name indicating its future activities. The company is about to erect a small laboratory, a concentrating unit, and a flotation machine at the smelter, in order to determine the lowest cost of dressing ores. A ball-mill is among the improvements. The smelter has immediate access to a large quantity of ore by aerial tram 3000 ft. long. It is proposed to develop this ore. In addition to the mill and smelter the company is to operate two mills. One of these is at Ironton, and will treat ores from the Keno, Indiana, Guadeloupe, and other mines in that district. This custom milling will be a great advantage to these mines. Machinery for the mill will be hauled and erected as soon as roads permit. After the Ironton mill is in operation the Treasury mill will be started. The operating cost of this mill is low, as it is driven by water-power. The National Bell and Guston mines will supply the Treasury mill, being operated under lease by the Ouray Con. M. & R. Co. The new venture should be successful, as there are numerous mines in the Ouray district carrying rich silver ore, but are highly silicious, and present transportation and treatment charges reduce profits considerably.

Camp Bird has cut a vein 22 ft. wide, assaying \$30 per ton, to a point 10,800 ft. from the portal of the new tunnel.

Rico.—Fifty cars of ore was shipped from the district during April. The Rico Argentine continues to ship heavily to the Durango smelter.

Rico Wellington Mining Company reports for 1917 that it shipped 424 tons of copper ore, 1826 tons of lead-zinc ore, 709 tons of iron-sulphide ore, and 1687 tons of lead-

silver ore, all dry weights. The net value of these was \$105,589. Cash on hand at end of 1917 was \$2395. The future of the property is considered good. Development is to be largely increased. A compressor and drills are being added. Reserves of 45% pyrite are said to be extensive.

Telluride.—The bonus system in effect in San Miguel county was discontinued on May 15, and a flat wage-scale adopted. Machine-men in drifts will get \$4.75; machine-men in stopes, \$4.50; timber-men, \$4.50; timber-men helpers, trammers, shovelers, track-men, and miscellaneous mine labor, \$4. Board at company houses will continue to be \$1 per day. The companies concerned are the Tomboy Tramway & Tunnel, Liberty Bell, Primos Chemical, Colorado Superior, Belmont Wagner, Smuggler, Humboldt, and Tomboy.

IDAHO

Kellogg.—Caledonia Mining pays 3c. per share, equal to \$78,150, on June 5.

Mackay.—The Empire Mines Co. is shipping 200 tons of 5.5% copper, 4 oz. silver, and \$1 gold ore daily to Utah smelters. The lower levels are reported to show 12% ore. Another dividend may be paid in July. A 3-mile tram costing \$125,000 has been erected, connecting mine and rail. Cost of haulage will be reduced from 60 to 12 cents. In charge of F. A. Behling there are employed 175 to 250 men.

Mullan.—At 2050 ft. depth in the Morning mine of the Federal company 10 ft. of good ore has been cut. This development adds largely to the mine's reserves.

Wallace.—Tamarack & Custer paid 3c. per share, equal to \$53,287, on May 20. This makes \$106,574 for the current year.

KANSAS

Baxter Springs.—Production of the district last week was 638 tons of blende and 116 tons of lead, valued at \$30,140.

The Sunflower M. & M. Co., 7 miles west, is to erect a mill. Twenty drill-holes have shown 7.8 to 17.5% ore. H. B. Dooley is manager.

MICHIGAN

Houghton.—Copper Range pays \$1.50 per share June 15. This makes \$3 for the current year.

Hancock Consolidated Mining Co. reports as follows for 1917, through its superintendent, C. E. Weed: At No. 2 shaft, including 359 ft. of sinking, there was 7472 ft. of work done. No. 4 vein supplied 74.1% of the ore from this opening. Six electric locomotives—4 battery and 2 trolley type—are working on the No. 49, 53, 69, and 70 levels. At No. 7 shaft new work amounted to 2439 ft. For 8 months the ore was of good grade, thereafter it was poor, due to a 'bar' of waste 200 ft. wide. The mill stamped 302,725 tons of ore, averaging 13.223 lb. per ton (0.661%). The total yield was 4,005,882 lb. copper, an increase of 1,180,948 lb. The metal sold at 28.229c. per lb., realizing \$1,142,454. Of this, \$31,492 was profit. Current assets total \$236,650, and liabilities \$394,945.

The May copper production of the district is estimated at 18,000,000 pounds.

MISSOURI

Joplin.—Production of the region last week was 7508 tons blende, 43 tons calamine, and 1454 tons lead. These averaged \$48, \$30, and \$83 per ton, respectively. The value was \$486,381, making \$9,575,581 for 20 weeks. Missouri contributed \$114,577. The market is much livelier than of late.

Manhattan Zinc Co. is to erect a mill on a lease of the Cunningham estate, 7 miles north-west of this place. Twelve drill-holes show rich ore at a depth of 93 to 145 ft. B. M. Dougherty is manager.

MONTANA

Butte.—The High Ore mine of Anaconda has been closed for three months to permit of concreting the 3400-ft. shaft. This will cost \$75,000. The High Ore produces 1950 tons of ore daily.

Butte & Superior started hoisting from No. 3 shaft on May 16. Repairs to the Black Rock shaft are progressing well. In regard to the suit by the Elm Orlu company over extra-lateral rights, Judge G. M. Bourquin has set October 21 for the supplemental hearing. This is considered of great importance to Butte & Superior.

Davis-Daly pays its initial dividend of 50c. per share, equal to \$300,000, on June 20.

Report of Butte & Superior Mining Co. for the first quarter of 1918 shows that a profit of \$327,982 was made, compared with \$574,017 in the last quarter of 1917. The mill concentrated 135,877 tons of ore assaying 16.233% zinc and 6.346 oz. silver per ton. The mill recovery was 95.462%, an increase of 0.618%. Zinc in concentrate amounted to 42,112,311 lb. Costs dropped from \$10.2759 per ton to \$9.7374, this being in general charges, other departments rising.

Kendall.—Barnes-King Development Co. reports as follows for the first quarter of 1918: Gold returns and sundries totaled \$450,283. Of this, \$77,342 was profit. A dividend of \$40,000 was paid. Another of equal amount was paid on May 15. The balance at December 31, 1917, was \$232,247, and at March 31, 1918, \$182,955. There was 17,761 tons of ore mined. Development costs were \$2.08 per ton, a high charge; labor was unsatisfactory; and underground results were only fair. The April yield was \$58,500.

NEVADA

Goodsprings.—Ore shipments from this district in April are estimated as 3350 tons.

Midas.—The Elko Prince Leasing Co. (John V. N. Dorr of New York, president, and Lee D. Dougan, general superintendent) operates the property of the Elko Prince Mining Co. at Midas. The leasing company was organized by the Dorr Cyanide Machinery Co. and its successor the Dorr Company, to finance the building of a mill and operate the property until all the money was repaid, together with some old indebtedness of the Elko Prince Mining Co. Upon liquidation of all debts a new contract was made whereby the Elko Prince Leasing Co. continues to operate mine and mill. About 50 men are employed.

Pioche.—Prince Consolidated has let a contract to Walter Fitch, Inc., to sink a 2-compartment shaft to 500 ft. This will be done by sinking from surface, and raising from the 300, 400, and 500-ft. levels already opened in the mine. This shaft will intersect the main incline at 500 ft. Litigation pending between the Prince Con., Virginia-Louise, and Davidson companies has been settled. The Davidson is now practically owned by the Prince. There was a counter appeal against the Virginia-Louise. The Prince has agreed to haul Virginia ores over its nine-mile railroad at 50c. per ton.

Sodaville.—Under this heading in the 'Press' of May 18 it was stated that certain people, including Mark Young, were developing tungsten claims here. Instead of Young it should have been E. T. Heggland.

Virginia City.—The threatened miners' strike was averted last week by an agreement being made whereby all underground workers and top carmen will receive \$5 per shift during the period of the War.

NEW MEXICO

Deming.—The Republic M. & M. Co. shipped 14 cars of high-grade zinc ore to Philadelphia in April. O. Weiser is manager.

Santa Rita.—Chino Copper Co. reports as follows for the first quarter of 1918, compared with the last period of 1917:

	1st quarter 1918	4th quarter 1917
Overburden removed, cubic yards...	833,241	588,653
Ore milled, tons.....	1,011,500	934,000
Copper content, per cent.....	1.6243	1.6388
Recovery, per cent.....	63.06	66.20
Copper production, pounds.....	20,721,217	20,266,715
Cost, cents per pound.....	15.28	13.65
Operating profit.....	\$1,124,254	\$2,282,167
Dividends paid.....	1,304,970	1,739,960
Deficit or surplus.....	- 180,716	+ 542,207

A. L. Owens and others have taken lease and bond on Royal Memphis Mining Company's property in the Black range and will at once employ 30 men. A 100-ton plant includes a standard 4 by 5-ft. ball-mill, five Wilfleys, and four Joplin Risley tables. Ore contains zinc, lead, silver, and copper. Estimate of ore-reserves and probable is 75,000 tons. Shipments have been made to El Paso smelter.

OKLAHOMA

Miami.—The northern part of this district is receiving considerable attention now, and the Tulsa Metal, Green Mining, Miami-Douhat Mining, Western Mineral, and Grant-Walker companies are busy drilling or erecting plant.

Picher.—Production last week totaled 5543 tons of blende and \$71 tons of lead, valued at \$341,664.

OREGON

Gold Hill.—J. G. Davies of Sacramento, lessee of the Sylvanite gold mine, has purchased the electrically-driven 10-stamp mill formerly operated on the Gray Eagle mine north of Gold Hill on Sardine creek, and will place the equipment on the Sylvanite. This mine has been a steady producer of rich ore since the first of the year. The mill will treat the present output until contemplated development is completed, when a larger plant will be erected.

Harbor.—Theo. R. Heintz, manager for the Chetco Mining Co., operating the Mt. Emery gold mine 12 miles east of this place in Curry county, reports that operation has been suspended due to trouble in securing supplies, principally gasoline.

Rogue River.—Recent developments have uncovered a large deposit of 17 to 42% manganese ore 11 miles from this place on Evans creek. The property is under lease to M. S. Johnson of Gold Hill, who will ship some ore and dress the lower grade ore.

Selma.—Daily brothers and John Casey of Selma are operating chrome mines on the Illinois river.

SOUTH DAKOTA

Lead.—Tunnels for hydro-electric system of Homestake Mining Co. were driven in fast time last year, according to 'Engineering News-Record.' W. B. Arndt was contractor. Iron Creek tunnel is 1097 ft., and Long tunnel 3931 ft., plus a 17-ft. adit, a total of 5045 ft. Rock was medium hard limestone, save 200 ft. of hard flint. Tunnels are about 7 by 8 ft. over all. Work was conducted from 6 headings. Nine jack-hammers were used in drilling, air-pressure ranging from 90 to 120 lb. Usual layout was four 7-ft. cuts and ten 6-ft. side-holes. Cross-bits on $\frac{1}{2}$ -in. hexagon steel and $\frac{1}{2}$ -in. 60% powder were used. In one period of 41 days, slightly over 1000 ft. was driven; in another of 23 days with 3 shifts, 350 ft.; and in another of 86 days, 1543 feet.

Rapid City.—South Dakota School of Mines 'Pahasapa' quarterly is a petroleum number. An unbiased discussion of subjects pertaining to oil production was deemed necessary. Regarding oil and gas lands in Fall River county,

South Dakota, Le Roy Eastman discusses their development. In 1903 a large area was secured, and strong gas flows were encountered, but soon died down. In 1913 the Ardmore Oil Co. of Ardmore drilled 1400 ft., but the Dakota sandstone was not reached. In 1918 the company is now reorganizing, and may drill to 2200 ft. Ten miles south-east of Hot Springs two companies are to start drilling in the spring. North of Ardmore a company is down 1500 ft., while two others are down 300 to 650 ft. Well-marked strata in South Dakota are the Bad Lands, Erskine, Minnekahta, Teepe Creek, Slim Buttes, and Ardmore-Rumford.

TEXAS

Alpine.—The smelter that the Metal Products Co. is constructing here will be finished soon. It will receive ore from the mines of the upper border region of Texas. Later on, when conditions in Mexico are more settled, and the Kansas City, Mexico & Orient railroad is extended south-west to a connection with its line that runs from Chihuahua toward the Rio Grande, the new smelter will be able to handle much ore from the mines of that country. The plant will cost \$125,000 and is intended as the first unit of a much larger one.

UTAH

Alta.—The Columbus-Rexall mine, which has produced 4500 tons of copper-silver ore netting \$126,000, is estimated to contain 12,000 of ore worth \$25 per ton. The company is free of debt, has \$20,000 in its treasury, and has supplies worth \$20,000. When roads permit, 30 tons daily will be sent to the smelters.

Gold Hill.—Western Utah Copper Co. report for 1917 shows an operating profit of \$133,019, and net profit of \$86,086. Earnings amounted to \$471,478, and expenses \$338,459. Current assets total \$66,721, and liabilities \$7556. The general manager, Duncan MacVichie, states that principal work and production was at the Gold Hill claims. Openings covered 5702 ft., on the 80, 110, 300, and 400-ft. levels. A good quantity of copper ore was exposed on the first two levels, some good silver-lead at 110 ft., and low-grade silver-lead on the lower levels. New equipment cost \$47,592. During 10 months of 1917, 28,718 tons of 2.98% copper and 4.33-oz. silver ore, and 3305 tons of 5.62% lead and 7.98-oz. silver ore was shipped. This yielded 1,710,984 lb. copper, 371,418 lb. lead, 150,767 oz. silver, and 70 oz. gold.

Green River.—Needles Mining Co., 25 miles south-west, has shipped 600 tons of 40 to 52% manganese ore this year. An output of 400 tons per month is expected soon.

Park City.—It is proposed to consolidate 800 acres of mineral land in the Morgan belt, supposed to be the northern extension of the Park City ore-bearing zone. The properties involved are the Morgan-Crescent, Boston-Utah, and Iron King, which were controlled by G. T. Stenhouse.

Tintic.—Chief Consolidated reports for the first quarter of 1918 a profit of \$276,826. Two 10-cent dividends have been paid this year, including one on May 6. Development covered 3231 ft. There was 16,668 tons of lead and zinc-lead ore mined, averaging \$48.32 per ton. Cash on hand amounts to \$419,915.

VIRGINIA

Richmond.—Possibilities for manganese ore on certain undeveloped tracts in Shenandoah valley, Virginia, are discussed in Bulletin 660-J of the U. S. Geological Survey, by D. F. Hewett, G. W. Stose, F. J. Katz, and H. D. Miser. North-western Virginia has been the source of much of the manganese ore mined in the United States, and has been the scene of active prospecting. In the belt investigated the well-known Crimora mine occupies a central position. The known manganese deposits in this part are masses of

oxides associated with rocks of different types and have diverse structural relations. Some bodies are pure enough to be mined and shipped without preliminary treatment. Others are composed of nodules disseminated through clay, and must be washed before shipment. Rocks with which the ore is associated include sandstone, shale, limestone, and dolomite, and the older crystalline rocks on which these rest. Tract 1, near Elkton, has indications to suggest

NORTHERN VIRGINIA, SHOWING UNDEVELOPED MANGANESE AREAS

that further prospecting should be done on it. Tract 2 should be thoroughly prospected by drilling. In tract 3 prospecting should be confined to the area between Naked and another creek. Tract 4 is worthy of drilling and test-pits, also some work on No. 5 and 6 areas. These places are indicated on the accompanying map.

WASHINGTON

Chewelah.—The Northwest Magnesite Co. has placed a third kiln in commission, has a fourth ready for erection, and will construct two more. A coal-pulverizing plant is now at work. Powdered coal is used in place of fuel-oil.

Kiesling.—The Spokane Tin Mining Co. has developed good ore to a depth of 152 ft. A concentrator is to be erected. F. C. Bailey has an option on the mine, which is in Spokane county, for 3 years at \$75,000.

Republic.—The Lone Pine Star-Surprise Consolidated Mining Co., operating the last Chance mine, is shipping 300 tons per week, according to Charles P. Robbins, general manager. This may be compared with 1000 tons per month early in the year. More than 1500 tons of ore is broken in stopes, against 1900 tons on April 1. A number of surface improvements are under way.

CANADA

British Columbia

Kaslo.—The Cork-Province Mining Co. has erected a ball-mill and flotation plant, costing \$15,000. The mill will crush 75 tons in two shifts. The flotation unit will dress zinc-silver tailing. W. E. Zwisky is in charge.

Nelson.—Charles F. Caldwell, president of the Independent Mine Owners and Producers' Association of the Kootenai, is arranging a meeting of the Association for about June 1 at Nelson. Members of both the Provincial and Dominion parliaments are expected to attend. The Canadian Pacific Railroad Co. is said to be in sympathy with the owners and will probably be represented, making the meeting one of great interest and importance. Smelter rates and general subjects that the mine-owners must study will be considered.

Trail.—A significant notice was issued recently by the Consolidated Mining & Smelting Co. to its employees, as follows: "Large increases in the various items entering into the mining and smelting of the Rossland (B. C.) ores, such as wages, cost of explosives, coke, steel, general mine and smelter supplies, without adequate compensation in values by way of increased metal prices, coupled with increased taxation, has made it necessary for the company to suspend shipments from the Rossland mines indefinitely. An endeavor will be made to keep a small force on development work, and to place the remainder of our Rossland employees at the smelter, the Sullivan mine, Kimberley, and other lead-silver properties of the company." The explanation of the above is found in the fact that the Rossland ores contain but a few pounds of copper per ton, the value being mostly in gold. It is the intention, therefore, to make shipments just sufficient, with the augmentation of custom ore, to keep one copper furnace at Trail in operation. One of the company's officials put it succinctly when he said: "As a gold dollar will hardly buy half as much as before the War, there appears to be no great advantage in mining gold ores at this time, especially when almost every variety of mining cost has doubled and more."

Ontario

Cobalt.—Kerr Lake produced 201,000 oz. of silver in April. For the four months the output totals 816,894 oz., against 891,698 oz. in this period of 1917.

Nipissing produced silver worth \$329,617 during April. This makes \$1,240,230 for the current year, against \$960,545 in the same period of 1917. The high-grade mill treated 210 tons and the low-grade plant 7023 tons.

Until more ore is blocked out the Temiskaming mill will be closed.

Kirkland Lake.—The Elliott-Kirkland company's shaft is down 515 ft. At 525 ft. a station will be cut and cross-cutting started to the vein.

The Teck-Hughes mill treated 1969 tons of \$5.86 ore during April.

Porcupine.—The Newray mine is now being developed by the McIntyre-Porcupine company under the new arrangement.

McIntyre-Porcupine company will pay a dividend of 5% on June 15, equal to \$180,000.

Quebec

Amos.—The Indian Peninsula Mining Co. is to operate the molybdenite property of the St. Maurice Mines Co. in the Hurricanav River district, near Amos on the transcontinental railroad. Frank Groch, W. E. Simpson, and P. G. Grant are largely interested. These shafts are to be sunk on the deposits.

The U. S. Bureau of Mines announces the following appointments:

C. H. Beal, petroleum technologist of the Bureau, who has been stationed at the Washington office for the past two years, has been transferred to the San Francisco station. He is to make an extended trip through the Mid-Continent field. M. J. Gavin, formerly chemist for the Shell Oil Co. of California, with headquarters at Oilfields, has recently received an appointment as assistant refinery engineer with the Bureau. J. M. Wadsworth, petroleum engineer for the Bureau, with headquarters at San Francisco, has returned from a two months' trip to Washington and other Eastern cities where he has been making fuel-tests for the Bureau. E. W. Wagy, petroleum technologist for the Bureau, with headquarters at San Francisco, spent March and April in Colorado and the Mid-Continent fields, co-operating with State officials in making investigations of the conditions of the wells in the Boulder field.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

G. L. Sheldon, of Ely, Nevada, is in Beaverhead county, Montana.

O. G. McKinney's address is desired by his sister, Mrs. L. J. Lassell, Kingman, Arizona.

J. H. McMichael, manager for El Potrero Mining Co., Sinaloa, Mexico, is in San Francisco.

A. G. McGregor, smelter construction engineer, left Lima, Peru, for the United States on May 2.

William S. Evans is now with the E. I. du Pont de Nemours & Co., at Wilmington, Delaware.

E. F. Gordon and B. B. Boeircck, of Boulder, Colorado, are examining mines in the Ely district, Nevada.

T. A. Rickard addressed the Utah section of the A. I. M. E. at Salt Lake City on May 29, his topic being 'Americanization.'

Maurice W. Summerhayes, former manager of the Porcupine Crown mine, is now manager for the Bluestone Copper Mining Co. in Nevada.

W. J. Trerise, formerly with the Morococha Mining Co., Peru, has been seriously wounded in Europe and honorably discharged as unfit for further service.

William C. Russell, who since the closing-down of the Caribou mine near Boulder has established an engineering office in Denver, is at present making oil-shale examinations in Garfield county, Colorado.

E. E. Vanderhoef, for the past ten years superintendent of steam-shovel operations of the Nevada Consolidated Copper Co., has accepted a position with the United Verde Copper Co. at Jerome, Arizona.

H. W. Morse, for the past five years with the Western Precipitation Co., has severed his connection to become technical manager for the American Trona Co., succeeding C. P. Grimwood. Mr. Morse will retain his official connection with the Western Precipitation Company.

Obituary

C. H. Rowland died at London on April 13 from wounds received at the battle of St. Quentin on March 22. He enlisted in the Royal Engineers in South Africa in 1915. Rowland was well known in South Africa, and at the time he enlisted he was superintendent of one of the large mines there. He leaves a widow and daughter.

F. R. Hutton, emeritus professor in Columbia University, and honorary secretary of the United Engineering Society, died at New York two weeks ago. He was known to a wide circle of engineers as the author of several standard treatises on mechanical engineering, particularly in connection with steam and gas-engines. In addition to other extensive publications he collaborated in the work of compilation for the Century Dictionary and the New International Encyclopedia. He was professor of engineering at Columbia from 1877 to 1907, and also served, in a consulting capacity, the Department of Water, Gas, and Electricity of the City of New York.

The U. S. Civil Service Commission announces an examination for the position of special agent to investigate general commercial and economic conditions in Mexico, Colombia, Venezuela, Bolivia, and Paraguay. The salary will not exceed \$10 per diem and \$4 for subsistence. Application forms and further information may be obtained from the secretary of the Twelfth Civil Service District, Room 241 Post-Office Bldg., San Francisco.

THE METAL MARKET

METAL PRICES

San Francisco, May 28

Aluminum-dust, large and small lots, cents per lb.	65-70
Antimony (wholesale), cents per pound, in small quantities.	10
Copper, electrolytic, cents per pound, in carload lots.	23 1/2
Copper, electrolytic, cents per pound, in small quantities.	24 1/2
Lead, pig, cents per pound.	7 1/2-8 1/2
Platinum, Government price, per ounce.	\$105
Quicksilver, per flask of 75 lb.	\$110
Spelter, cents per pound.	9 1/2
Zinc-dust, cents per pound.	17 1/2

ORE PRICES

May 28

Antimony, 45% metal, f.o.b. California, per unit.	\$110
Chromite, 38% and over, California, per unit.	\$1.25-\$1.50
Magnetite, crude, California, per ton (nominal price).	\$7.00-\$8.00
Manganese, 40 to 50% Mn, Hazen, Nevada, cents per unit.	92-110
Manganese, 48% New York, per unit.	\$1.20
Molybdenite, per lb., 90% MoS ₂	\$1.25
Pyrite, domestic, New York, cents per unit of sulphur.	28
Tungsten, 60% WO ₃ , California, per unit.	\$24

EASTERN METAL MARKET

(By wire from New York)

Up to the time of going to press our New York metal telegram had not arrived, but there have been no important changes in prices.

COPPER

On September 21, 1917, the Government fixed copper prices at 23.50c. per lb. for large lots, and 24 1/2c. for small lots, effective until June 1, 1918. Quotations in cents per pound are as under:

Date	Average week ending

May	29.02	31.69	Nov.	31.95	23.50
June	27.47	32.57	Dec.	32.89	23.50

The War Industries Board has recommended that the present price of 23 1/2c. per lb. be continued for 3 months after June 1. The Shannon, Mass., Victoria, Lake, Franklin, Cuba, Nevada-Douglas, Ohio, Tennessee, and Adventure companies asked for a higher price on account of their steadily rising costs.

Copper production of the 'big four' mines in April, together with the first quarter's output and copper sold, is as under, in pounds:

Mine	April 1918	First quarter 1918	Copper sold in quarter
Chino Copper	6,290,513	20,721,217	14,033,129
Nevada Con.	6,900,000	17,433,164	5,989,808
Ray Con.	7,350,000	22,750,677	12,502,872
Utah Copper	16,690,883	41,276,750	27,066,505

Nineteen of the largest producers in North and South America and Mexico yielded 138,614.112 lb. in April, while for 4 months they returned 540,482,289 lb., against 552,771,537 lb. in this period of 1917.

SILVER

Below are given official (not Government) quotations, in cents per ounce of silver 999 fine. In order to make prompt settlements with smelters and brokers, producers allow a discount from the Government price of \$1, hence the lower price. The Government has not fixed the general market price at \$1, but will pay this price for all silver purchased by it. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the current rate of exchange.

The price of silver in London is practically stabilized. The Shanghai exchange has eased somewhat, and is much below the parity with silver.

Reserve of silver coin and bullion in India was 1044 lacs of rupees on April 7, 1918, lacs on the 15th, and 1169 lacs on the 22nd (the last figure is equal to \$37,410,000). The German Reichsbank reports silver holdings of 130,000,000 marks (\$30,000,000 nominal), an increase of \$104,000,000 (\$26,000,000) in a year.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound. On May 25, 1918, the Government fixed prices until September for grade A spelter at 12c. per lb. for itself and the open market. This grade constitutes only a small proportion of the total output. Lower grades can make their own prices as usual. Sheet zinc is fixed at 15c., and plate at 14c. per pound.

Cost of producing lead by the Bunker Hill & Sullivan last year was 6.64c. per lb. The average price realized was 8.73 cents.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. The Government is taking 40% of the United States quicksilver output, paying therefor \$105 per flask. Outside of this business the competitive market can make any price as usual. Prices, in dollars per flask of 75 pounds:

Date	May 14	May 21

Mineral production of the United States, expressed in percentages of domestic demand (100%), as estimated by Director of the Geological Survey, is:

Antimony	10	Mica	38
Arsenic	60	Molybdenum	over 100
Chromium	37	Platinum	13
Corundum and emery	90	Potash	10
Graphite	25	Pyrite	33
Graphite for crucibles	99	Sulphur	103
Malachite	99	Tin	14
Manganese	100	Tungsten	65
Mercury	120	Vanadium	over 100

Eastern Metal Market

New York, May 22.

Activity is moderate in all the markets, but there is a strong undertone in most of them.

Copper is fundamentally unchanged, pending a decision as to a future price.

Tin is extremely quiet, with offerings decidedly limited, and the price situation a little easier.

Lead is stronger, with the entire situation encouraging.

Zinc exhibits a firm tone, and is higher.

Antimony is quiet and unchanged.

In the steel industry it is evident that there is no escape from the fact that little steel can be had for ordinary consumption this year, if all the steel in the surprising total made up by the War Board can be supplied to ship, projectile, track, car, locomotive, structural, and other war uses in the specified delivery period. The month of May now promises to show the largest production in the past year period of both pig-iron and steel ingots. The most serious factor in the situation is the loss of three months' time in placing locomotive and car-orders. The Midvale Steel & Ordnance Co. is about to build and operate for the Government a great plant at Nicetown, Pennsylvania, to make 16-in. howitzers. Among the price adjustments announced on May 21 is an advance of \$6 per ton on cast-iron water-pipe. In the labor situation the interesting fact is announced that the Midvale Steel & Ordnance Co. will take up the proposal to introduce women into its machine shops at Nicetown and its wire mills at Johnstown, Pennsylvania, to provide against a prospective shortage of men.

COPPER

A meeting, to which the entire copper trade is directing its attention, is being held in Washington today between the copper producers and the War Industries Board to discuss finally the price to obtain for copper after June 1. It is impossible to forecast any result of this meeting, which may last several days. All sorts of predictions are heard in the trade, many of which are conflicting, of course. It seems that the preponderance of opinion is that an advance will be decided upon, but how much is the question. A rumor is current to the effect that a compromise will make it 24.25c., or an advance of $\frac{1}{4}$ c. per lb. over that which has obtained since last September. This compares with 25c. asked for or expected by some. The demand continues strong, with that for June nearly as large as that for May, with some difficulty ahead to supply it. Consumption is on a tremendous scale, with foreign demand recently on the increase. Bookings for delivery after June 1 are being made, with the price stipulated as the one ruling at that time, indicating an expected change. Exports are still small as compared with a year ago, those for April being reported as 21,528 gross tons, against 49,536 tons in April 1917. Each month thus far this year they have been less than in the same months a year ago. The total to May 1, 1918, has been 112,775 tons, as compared with 184,341 tons to May 1, 1917.

TIN

The market for future shipments is slightly easier, but offerings in general continue limited. In the last week, or since the last letter, there have been a few offerings of June-July shipment from the Straits which were readily sold, the price being about 93c. per lb. This is lower than sales made recently, which had been at 96 to 97c. The easier market, though limited in quantity, is due to a report that one steamer of Banca tin had been allowed to sail from Batavia, with others also about to sail. Nothing definite is known,

however, and the Banca situation is up in the air, because on Monday another report came that the vessel had not actually sailed but was loading, and that some trouble about licenses was brewing. The spot market continues unrelieved. It is nominally quoted at \$1.03 per lb., New York, with metal virtually unobtainable. Arrivals to May 16, inclusive, have been 800 tons at Atlantic ports, with 5000 estimated afloat. The London market is lower at £360 per ton for spot Straits, against £375 a week ago.

LEAD

The lead situation is more encouraging than in recent weeks, and the market has strengthened considerably in the last week. There have been fair sales, and a liberal inquiry from Canada. Buyers are coming into the market for small lots more numerous and also for some good sized ones. It is, however, reported as difficult to obtain prompt or May lead. Yesterday the market was quoted at 6.95 to 7c., New York, or 6.80 to 6.85c., St. Louis, for early delivery, with spot metal held at 7.25c., New York. The American Smelting & Refining Co. maintains its price at 7c., New York, unchanged for some weeks. The stronger technical position is due to the fact that the excess quantity that was being offered recently has been absorbed.

ZINC

The market has gathered strength, if anything, in the past week and the tone continues firm and cheerful. Prices have advanced, although inquiry and sales have not expanded, but rather have declined. The technical position is strong. The quotations on prime Western for early delivery are 7.25 to 7.37 $\frac{1}{2}$ c., St. Louis, or 7.50 to 7.62 $\frac{1}{2}$ c., New York. Sales have been made at the lower levels. For forward delivery there is less disposition to sell, despite some willingness to buy, and for these positions a premium of about $\frac{1}{4}$ c. per month is asked. There has been considerable interest manifested in the meetings that have been held recently in Washington relative to a fixed price of grade A which is effective to June 1. It is probable that a decision was reached not to change the present maximum price of 12c. per lb. for it is known that the Government has purchased quantities under this maximum. It is reported that 1000 tons of grade C was bought by the Government in the last week, but the price involved is not known publicly. April exports of zinc are returned as 7638 gross tons.

Sheet zinc is fixed officially at 15c. per lb. with 14c. as the price of plate zinc.

ANTIMONY

The market is unchanged at 12.50 to 12.75c., New York, duty paid, for Chinese and Japanese grades with the tone easier. The Government is reported to have bought recently about 1000 tons.

ORES

Antimony: There have been no developments and no business reported.

Manganese: As high as \$1.35 per unit has been paid for Indian manganese ore for delivery in this country.

Molybdenum: There has been quite a little activity, with quotations \$1.25 per pound of MoS₂ in 90% concentrates.

Tungsten: The market is firm at \$24 per unit in 60% concentrates for both scheelite and wolframite and sales have been made at these prices. Lower grades have brought \$20 to \$23 per unit. It is stated that a hearing will be held at San Francisco in the week of June 24, when the U. S. Tariff Commission will discuss tungsten, quicksilver, and antimony. Price fixing in these minerals and metals will probably be postponed until after this.

Company Reports

Following are abstracts from the 1917 reports of the disseminated-copper companies:

CHINO COPPER CO.

Property: mines at Santa Rita and mill at Hurley, New Mexico.

Operating Officials: J. M. Sully, general manager; Horace Moses, superintendent of mines; F. R. Wicks, superintendent of mills; G. L. Webster, cashier.

Financial Statement: operating revenue was \$19,261,306, less \$9,434,690 for expenditures. Adding \$310,436 miscellaneous income and deducting \$624,198 for alterations, depreciation, etc., the profit was \$9,512,854. Adding balance of \$13,963,874 from 1916, there was available \$23,476,728. After paying dividends there was carried forward to 1918 the sum of \$14,863,926. Current assets total \$10,962,576, a decrease of \$225,767, and liabilities \$8,829,255, a decrease of \$876,325.

Dividends: four, equal to \$9.90 per share, absorbed \$8,612,802.

Development: the mining property was increased to 3010 acres during the year by acquiring 100 acres. Churn-drilling amounted to 22,425 ft., making 249,728 ft. to date. Overburden stripped by steam-shovels totaled 3,712,414 cu. yd., making a total of 20,599,199 cu. yd. Reserves of ore are estimated at 95,555,843 tons, averaging 1.656% copper.

Production: the mill concentrated 3,608,100 tons of 1.64% ore, equal to 9885 tons per day. This yielded 264,756 tons of 15.47% concentrate, which, with ore smelted direct, returned 83,339,782 lb. copper. This was a gain of 7,567,604 lb. over that in 1916. Two units were added to the mill, giving it a daily capacity of 11,000 tons. Another unit was built at the primary crushing plant at the mine, also a turbo-generator erected in the power-plant. In section 7 of the mill oxide and semi-oxide ore is to be treated

Costs: These were as under, on a per ton basis:

	1917	1916
Steam-shovel operations	\$0.5088	\$0.3797
Milling	1.0300	0.6400
On a per pound basis:		
Total cost	0.1139	0.0870

INSPIRATION CONSOLIDATED COPPER CO.

Property: mines and mill of 20,000 tons daily capacity at Miami, Arizona.

Operating Official: C. E. Mills, general manager.

Financial Statement: sales of copper in 1917 realized \$21,242,217. Expenses totaled \$11,653,588 and depreciation \$750,000, leaving a profit of \$10,903,588, plus \$177,144 for interest, equal to \$11,080,732. Current assets are placed at \$19,161,430, and current liabilities, \$4,678,484. Balance from 1916 was \$12,681,501, plus profit for 1917, making \$23,762,233 available. After paying dividends the surplus carried to 1918 was \$14,011,005. Federal taxes last year amounted to \$1,185,249, already deducted.

Dividends: four of \$2 each and a special of 25c., amounted to \$9,751,238.

Development: 21.05 miles were driven underground, making 112.97 to date. During 1917, 22.73 miles of openings were destroyed, leaving 59.08 miles open at end of the year. No new ore was developed, so reserves are the same, less the amount mined, leaving 87,864,378 tons available. The average output per shift was 17.26 tons per man.

Production: from early in July to August 23, labor troubles resulted in a complete cessation. By March 1918 full capacity was attained. The concentrating plant dressed 3,891,075 tons of ore carrying 1.388% copper, of which 0.279% was in the form of oxide. Recovery of sulphide was 89.73%, reduced to 75.34% when calculating all copper.

Concentrates produced 79,346,033 lb. copper, and oxide ore smelted direct 1,220,949 lb., making a total of 80,566,982 pounds.

Costs: these were as under:

Department	Per pound cents	Per ton
Mining	3.572	\$0.7239
Coarse crushing	0.163	0.0329
Ore hauling	0.101	0.0206
Concentrating and royalty	2.931	0.5941
Concentrate freight	0.007	0.0015
Smelting, marketing, etc.	3.665	0.6369
Total	10.439	\$2.0699

Mill statistics are given on page 764 of this issue.

MIAMI COPPER CO.

Property: mine and mill at Miami, Arizona.

Operating Officials: R. B. Gottsberger, general manager; F. W. MacLennan, assistant manager; F. W. Solomon, mill superintendent; R. B. Yerxa, assistant mill superintendent.

Financial Statement: during 1917 a profit of \$4,952,137 was made. The revenue from metal sold was \$9,009,152. Current assets, including metals \$1,721,784, total \$6,240,846, and current liabilities \$1,187,565.

Dividends: four quarterly and one special, equal to \$8.75 per share, totaled \$6,537,247. Since 1912, \$16,233,031 has been distributed.

Development: labor troubles resulted in a complete suspension for 7 weeks. New work amounted to 25,476 ft. On the Captain orebody 9406 ft. was done. A new extraction level—the 345 ft.—was opened to maintain tonnage. Shrinkage-stopping and caving are used here. In the eastern portion of the mine top-slicing is the method of mining. No. 2, or the 570-ft., haulage-level is open for the area being worked. A new shaft is being sunk, known as No. 5. No. 4 has been the only outlet for ore, and its crushing plant is overworked. The new shaft is being lined with concrete, and a crushing plant will be erected. With two such plants clean sulphide ore and oxide ore can be separated. Reserves of all classes total 48,760,000 tons, averaging 1.581% copper.

Production: re-modeling of the mill continues. Last year it concentrated 1,640,206 tons of 2.032% ore, yielding 53,639 tons of 43.04% product, containing 46,172,322 lb. Recovery was 69.25%.

Costs: these totaled 12.511c. per pound, against 9.520c. in 1916.

NEVADA CONSOLIDATED COPPER CO.

Property: mines at Ely, and mill and smelter at McGill, Nevada; also control of the Nevada Northern Railway Co.

Operating Officials: C. B. Lakenan, general manager; W. S. Larsh, underground superintendent; E. E. Vanderhoef, shovel-pit superintendent; G. C. Riser, concentrator superintendent; R. E. H. Pomeroy, smelter superintendent; C. V. Jenkins, business manager. (Mr. Vanderhoef recently resigned.)

Financial Statement: sales of ore and metals in 1917 realized \$20,279,723. Operations cost \$11,635,375. With income from other sources and balance from 1916 there was available \$22,291,242. Dividends, ore extinguishment, alterations, etc., left a balance of \$13,180,526. The year's profit of \$9,408,893 was \$6,026,467 lower than in 1916. Current assets total \$16,834,891, and liabilities \$2,533,468.

Dividends: these totaled \$8,297,747, making \$35,771,603 to the end of 1917.

Development: churn-drilling—67 holes—to an average depth of 417 ft. totaled 27,902 ft. Drills at Copper Flat showed 6,355,726 tons additional ore, assaying 1.457%; while at the Ruth mine reserves were decreased by 256,072 tons of 2.25% ore. Reserves at the end of 1917 totaled

70,025,322 tons, averaging 1.58%; plus 864,199 tons of 2.02 to 3.89% at the Kimbley, Wedge, and Veteran mines; also 174,648 tons of 2.5% carbonate ore used as flux. Steam-shovels stripped 2,998,025 cu. yd. of overburden. The Ruth mine is now equipped to hoist 4000 tons daily. Last year it contributed 32% of the total ore mined. Improvements at the mines included a new steam-shovel, locomotives, cars, hoist, compressor, and pumps.

Production: improvements to the mill were completed during the year. There was concentrated 4,064,095 tons of 1.462% ore, of which 73.08% was recovered. Concentrate assayed 7.673%. For the Consolidated Coppermines Co. the company handled 175,424 tons averaging 1.36%. Twenty-four roasting-furnaces were worked, an increase of two. They are all fitted to use coal in place of oil, as were also the reverberatory furnaces. The converters yielded 82,040,508 lb. copper, against 90,735,287 lb. in 1916. In the power-plant, a 3000-kw. turbo-generator, 20,000-cu. ft. turbo-blower, and triple-expansion pumping engine are being installed.

Costs: a comparison of the past two years follows; per ton:

	1917	1916
Steam-shovel mining (less taxes), cents..	18.90	12.42
Steam-shovel mining (all charges), cents.	63.38	53.70
Ruth underground (direct charge).....	\$1.0251	\$1.2021
Ruth underground (all charges).....	1.3751
Milling, cents	74.80	55.90
All costs, cents per lb. of copper.....	10.84	8.13

RAY CONSOLIDATED COPPER CO.

Property: mine at Ray, mill and smelter at Hayden, Arizona; also control of the Ray & Gila Valley Railroad.

Operating Officials: L. S. Cates, general manager; W. S. Boyd, superintendent of mines; D. D. Moffat, superintendent of mills; R. I. Ezell, cashier.

Financial Statement: operating revenue in 1917 was \$21,278,071, and expenditure \$11,299,415, leaving \$9,978,656 net. Adding miscellaneous income and deducting alterations and adjustments the surplus was \$9,701,170. The year started with a balance of \$13,813,178, ending with \$16,890,196. Current assets total \$13,045,764, an increase of \$2,044,466, and liabilities \$1,878,547, an increase of \$571,741.

Dividends: \$4.20 per share, totaling \$6,624,152 in 1917.

Development: general conditions at the property were never better at present. At No. 1 shaft new work covered 35,617 ft., at No. 2, 48,069, and at No. 3, 1229 ft. There are still intact about 60 miles of workings. Most of the work was on No. 3 level, to open the lower portion of the orebody. Owing to decomposed schist, the main tunnel for 1620 ft., station, and pocket were concreted. Reserves are 89,812,522 tons, averaging 2.048%.

Production: improvements at the plant were mostly devoted to dressing the fine material made by milling. There was concentrated 3,560,900 tons of 1.635% ore, making 16,782,600 tons of 1.678% to date. Concentrate averaged 24.37%. Recovery was 74.53%, against 72.20% in 1916, and 64.11% in 1915. The sulphide ore gave 83.32%, and the oxide 33.48%. Including ore smelted direct, the output was 92,207,356 lb., an increase of 18%.

Costs: mining cost \$1.04, which is 35c. higher than in 1916; coarse crushing, 4.66c.; milling, 82.86c. against 55.35c.; and all charges 12.29c., compared with 10.267c. in the previous year, per pound of copper.

UTAH COPPER CO.

Property: mines at Bingham and mills at Garfield, Utah; also control of the Bingham & Garfield Railway Co.

Operating Officials: R. C. Gemmell, general manager; J. D. Shilling, superintendent of mines; H. C. Goodrich, chief engineer of mines; F. G. Janney, general superintendent of mills; T. A. Janney, superintendent of Arthur mill; H. C.

Smith, superintendent of Magna mill; C. F. Jennings, assistant purchasing agent; J. M. Hayes, treasurer.

Financial Statement: metals sold realized \$48,797,423. Operations cost \$24,886,646. Other income totaled \$6,074,348, less \$1,289,630 for alterations, etc. Adding the balance of \$43,153,137 from 1916, there was available \$71,848,633. After paying dividend the balance to 1918 was \$48,293,528. Current assets total \$38,340,361, an increase of \$4,834,029; and liabilities, \$8,054,471, a gain of \$4,694,450. Book value of investments is \$12,604,002.

Dividends: five disbursements amounting to \$14.50 per share totaled \$23,555,105, making \$75,770,883 to date.

Development: churn-drilling in 11 holes totaled 840 ft. So far, 105 holes have been put down an average of 597 ft. Capping removed amounted to 4,271,868 cu. yd. The area actually stripped is 121 acres. Reserves are now 371,752,000 tons, averaging 1.33%. All concentrating ore was mined by steam-shovels. From the Sulphide mine there was extracted 38,708 tons of copper-lead-zinc ore.

Production: considerable improvements were made at the Arthur and Magna mills, including the fine-grinding department and new leaching plant. The average normal and metallurgical-economic capacity is 24,000 tons daily, but they were crowded to handle 34,362 tons. Both mills dressed a total of 12,542,000 tons, compared with 10,994,000 tons in 1916, 8,494,300 tons in 1915, and 6,470,166 tons in 1914. The average grade was 1.337%, and recovery 61.1%, both decreases. Copper from all sources amounted to 206,174,442 lb., a gain of 9,756,962 pounds.

Costs: mining, transportation, and milling rose to \$1.4170 per ton from 93.55c. in 1916 and 86.24c. in 1915; on a per pound basis the increase was from 6.95 to 10.995 cents.

The railway carried 34,653 tons daily, also 1838 passengers per day.

ALASKA JUNEAU GOLD MINING CO.

Property: mine and mill at Juneau, Alaska.

Operating Official: P. R. Bradley, general superintendent.

Financial Statement: the cash indebtedness, less the cash assets, was \$1,124,101 on March 1, 1918. Including \$459,359 from bullion and concentrate, the revenue in 1917 totaled \$490,049. Expenses, including taxes, interest, etc., were \$710,623. Expenditure on property and plant last year was \$806,314, making \$4,195,434 to date.

Development: in recent issues of the 'Press' the physical condition of the mine and plant has been fully discussed, so it is not necessary to cover the same ground again. A total of 23,741 ft. of development was done during 1917, making 76,063 ft. to date. The new work was confined chiefly to the north orebody along its westerly strike. This portion of the vein is more distant from the Silver Bow fault, and is not influenced by it. All samples from it show a good consistent average. The evidence now indicates existence of a large body in this section of the mine that will be free from large intrusions of waste, and will have a much higher recovery value than the mixed ore and waste now being drawn from the 400 stope. 'Muck' sampling to date from the entire mine—5303 samples—gave an average of 88.7c. per ton, and 409 moil samples since 1912 averaged \$1.64 per ton. No. 4 level—400 stope—yielded 91% of the tonnage last year.

Production: part of the new mill started in April 1917, but many troubles, already described in this journal, curtailed reduction seriously. There was treated 672,424 tons of ore assaying 87.5 cents per ton. Of this value, 33.88c. was free gold, and 31c. in galena concentrate. Extraction was 74.15%. Since 1914, inclusive, the old and new mills treated 1,092,455 tons of \$1.0095 ore. Extensive alterations are being made to the mill.

Costs: operations in 1917 cost \$1.1556 per ton, including 30.12c. for preparatory mining, 11.62c. for bulldozing, 43.87c. for crushing, and 5.3c. for concentrating.

THE Department of the Interior has evidently overlooked the fact that the Director General of Railroads is endeavoring to curtail tourist travel, judging by Newspaper Bulletin No. 113, extolling the beauties of the Zion National Monument in Utah, and the marvels of the Yellowstone Park and Crater Lake. Such advertising seems superfluous and out of keeping with the grave problems of war that confront us, as well as being a waste of clerical effort, of good paper, and of overcrowded postal facilities.

ACCCEPTANCE of the principle of a maximum base price is involved in the agreement between the War Industries Board and the producers of aluminum, in accord with which the highest price, beginning with June 1, will be 33 cents per pound in lots of 50 tons or more of ingot assaying 98 to 99% pure. The arrangement as made will endure for three months. The differentials for sheet, rod, and wire will be increased approximately 12½%, while differentials for quantity and grade, and those for alloy, will remain as approved by the Board in March.

RAILROAD rates are to be increased 25% in order to meet the expenses of operation. No doubt this action was necessitated, and we are able to sympathize with the Director General, who must have been reluctant to take such a step. It tends to increase severely the burdens of the West on account of the long haul. At the same time it adds to the complexity of those industrial operations in the East that depend upon Western copper, lead, chrome, and other raw materials. It also will make the cost of meats and sugar distinctly higher. In fact, it is part of an endless chain of growing costs that is magnified the longer it is continued. We venture to point out that it is largely the result of discriminative price-fixing. The market quotations represent normally a balance between supply and demand. In times so extraordinary as these it is evident that the law will work to the injury of the people and the Government unless some restraint be exerted. This was recognized, and the prices of certain articles were officially regulated. The inevitable effect was to disturb the course of business and to impose greater hardships upon the restricted industries. It is true, as President Wilson said in his address to Congress the other day, that the profiteers can be

reached by taxing their profits, but that does not save the public from being taxed first by the profiteers. The evil can also be corrected by introducing one rule for all and fixing the prices of all commodities. We are unable to see any other way by which the burdens of the people can be equalized. By cutting down exorbitant profits the Government can also reduce its own expenditures, which grow *pari passu* with the increase in market prices.

CANTIGNY is the first name to be associated with a notable exploit on the part of our soldiers in France. It is true that sundry raids and patrol affairs had been featured earlier by the daily press, but these had been rendered almost ridiculous by exaggeration. Cantigny is altogether different. The storming of this position near the point of the salient made by the Enemy's thrust at Amiens was a brilliant affair, to which the seal of resolute courage has been set by holding the ground against a series of savage German onslaughts. It is not surprising that the Enemy's bulletins try to ignore this part of the fighting, for he is unwilling to let his people know that the Americans have 'made good,' and more. Cantigny is destined to be the first of many French names that will be forever entwined with the story of American military support to the great cause for which the Allies are fighting against heavy odds in these critical days. The Berlin 'Tageblatt' may label the American troops "second-rate," but the jibe will prove as futile as that under which the "contemptible little army" of our Ally fought its way to undying fame.

PRICES for copper remain fixed at the old figures, 23.5 cents per pound for carload lots and 24.675 cents for smaller quantities. This will apply until August 15, when a new hearing is due the copper producers. Their recent experience affords no assurance that they will get it, since the War Industries Board is reported to have decided upon the price that is to rule for 75 days after June 1 before the conference with the producers was held. The plea of the small miner, to which we referred on May 25, has elicited the statement that consideration may be given to the problem of adjusting prices in harmony with the cost of production. This would afford relief, and probably would be accepted by the copper miners as a working basis. Nevertheless, it is necessary to progress cautiously in making such

regulations. We believe that jurists will agree with us in the opinion that a discrimination of this nature would be unconstitutional, unless it be conceded that in time of war all things are constitutional if done by a Government bureau. In the next place, a better price for copper from high-cost mines will set the labor unions busy equalizing the schedules, thus augmenting the difficulties as a snowball grows bigger the farther it is rolled.

OUR first lesson in the meaning of practical collectivism has been driven home by Secretary McAdoo. Shop-men on two important railroad systems, temporarily forgot the name of the concern for which they were working and struck. The Director General has written a kindly letter, and it is one that cannot be misunderstood. He reminds the workmen that a great army of their fellow citizens is confronting the foe in Europe and is dependent, in the face of grave peril, upon the earnest co-operation of all Americans in supporting their heroic efforts by sending forward an unbroken stream of supplies and ammunition. No strikes may be permitted at such a time. The sacrifice of the brave men suffering in the trenches and fighting day and night to protect their country, while only a pittance is paid to them as a token of the nation's gratitude, puts to shame the petty worries of men who live at home, who eat their meals in safety, and work under healthful conditions eight hours per diem. Incidentally, the labor unions have been asking to be freed from capitalism, and now the opposite system is being tried on a huge scale through Government control of the railroads. The first discovery made is that other forms of protest than the strike must be adopted when the complaint is against the people instead of a private corporation.

ZINC producers have suffered keen disappointment. Few of the metals felt so promptly the early demand arising from military needs; the prices swept from 10% below normal to 290% above, in the interval from July 1914 to June 1915, and they remained at a high level almost to the moment of our entering the War. The industry expanded proportionally, and mines were developed to an unwonted extent. The price, however, declined severely in the autumn of 1916, but a renewed demand was anticipated when war was declared by the United States. This failed to appear. No intimation of the probable requirements of the Government could be obtained, but many mines continued to operate at a loss in the hope of relief. When at last the Government took action the prices were fixed for the higher grades only, thus justifying the foresight of producers who had persisted in preparing to make electrolytic zinc. Recently a moderate demand for grade C has developed, but the outlook for heavy consumption of spelter by the Government is not encouraging. Consequently interest is being taken in developing new uses for the metal. The field for sheet-zinc to replace corrugated iron is attractive. At some mills preparations have been made to produce this material on a greatly enlarged scale. From Joplin comes

word of a concerted effort by a group of zinc producers to stimulate invention by offering special rewards for the disclosure of new applications. Three prizes of \$10,000 each are proposed for the first three practicable discoveries reported to the committee. Following these will be other prizes graduated from \$5000 for a new use that will consume 50,000 tons of zinc per year down to \$2000 for a new application involving a demand for 20,000 tons. The originator of the contest is Mr. F. C. Shoemaker, president of the United Producers Smelting Company, at Henryetta, Oklahoma.

REPRESENTATIVE KITCHIN has failed to display the shame that we believed he would feel when it was explained to him how his zone-postal law would help the cause of Kaiser Wilhelm. On the contrary, dispatches from Washington affirm that he charges a group of newspaper publishers, whose names apparently he hesitates to mention, with conspiring to influence congressmen to hold up the revenue bill until this law is repealed. Since Mr. Kitchen imputes motives we would like to ask him what has inspired his hostility to the free circulation of the organs of information in this country? Why was he afraid to introduce the postal-zone bill frankly and in the regular way, and let the light of publicity beat upon it? Why did he slip it through as a rider on a revenue bill at the last moment, and make its acceptance the price of his adherence to that vitally needed measure? How will the limitation of the sphere of influence of our great newspapers and magazines improve the intelligence of the people or draw them closer together in understanding sympathy? How will an increase in sectional feeling help to solidify the United States of America? Is it not true that intellectual intercourse and exchange of fact and opinions is essential for welding the populations of different sections into one people? Is not the accentuation of local ideas, unmodified by the views of other districts, equivalent to putting a premium upon sectional selfishness and jealousy? Is it not fair to ask Mr. Kitchen why he insists on a measure whose inevitable tendency will be to destroy the solidarity of his country? Is it not true that Germany will delight in sowing the seeds of sectional differences, which ultimately lead to animosities? Why does Mr. Kitchen persist in advocating a scheme that will redound to the advantage of our Enemy? He attributes motives to others; it is proper to demand from him an accounting as to his own motives. What are they?

PHOSPHATE-ROCK production dropped to the low level of 1,308,481 tons in 1915, and remained nearly stationary for two years. It has, however, returned to normal, being 2,003,991 tons in 1917, and the improvement has been sustained during the early part of the present year. The mines of south Florida have shipped 30% more in the last three months than during the same period of 1917. We are pleased to record this as a cheering evidence of two things regarding which opinion had differed in the absence of exact data; these are that fertilizer must have been available in practically normal

quantity for this season's crops, and that the output of sulphuric acid must have been greater than generally expected. It is certain that the phosphate miners will not produce far ahead of available shipping facilities, and fertilizer manufacturers will not buy the crude rock unless they have at command the acid for converting it. The combined quantities of imported Spanish pyrite and the increased tonnage from domestic mines correspond to the high level of acid production. How much of this acid is released for fertilizers can be judged only by the shipments of the raw phosphate. This is favorable for the crops of the present year, but we must not forget that the importation of Spanish pyrite will be reduced to 10,000 tons monthly by September, leaving a deficit of about 62,000 tons per month to be made good by augmenting the production of this country. We thoroughly approve the insistence of Mr. Philip N. Moore in his testimony the other day before the Senate Committee on Mines and Mining that the sure way to protect the country in a sufficient output of pyrite for supplying its vital needs is to fix the price for a period long enough to warrant the necessary outlay in development and equipment of mines. From all sides, from the prospector, the capitalist, the engineer, comes one accordant voice on the need of price-fixing for the essential minerals specified in the War Minerals Bill. Let Congress heed the opinion of those that are best informed, and put the Bill through at this session with the price-fixing power retained. Without that it will be of secondary importance, and the Government will have to fall back on the provision that allows it to turn prospector and miner in the effort to supply the necessities of war.

Carrying the Message to Russia

Ukrainia is not at peace under the 'benevolent' despotism of the German militarists. Whatever the nobles in southern Russia may think of the Teuton, who promises them salvage of their estates from the turbulent anarhist, the common people see in the invasion of the blonde savages of the north only robbery and destruction. They prefer to starve by their own acts than to die that German looters may live, so they destroy the grain they cannot hide for surreptitiously sustaining the families dependent upon them. Throughout Russia the light of disillusionment is breaking upon the peasants. They had always distrusted the socialistic agitators and had declined to make common cause with them. We have the written authority of the two ablest and best informed political reformers in all Russia for that, namely, Leo Tolstoi and Paul Miliukov. The peasant, however, knows land; he yearns for free land and more land; it was on this sentiment that Ivan the Terrible played when he undertook to crush the turbulent nobility and strengthen his hold upon an expanded Muscovy. It was in the face of this fear of the conniving few, who preached reform while aiming at personal aggrandizement, that the vigorous butcher Menin rallied the land-tillers to secure their holdings under an emperor

picked from the ranks of the plain people and had the first Romanoff elected in a popular assembly to rule with unlimited power. That was in the days when democracy as we understand it had not been tested, and the idea of the people was that an autocrat who owed his elevation to them was safer than wrangling congresses composed of men devising ways to rob the helpless peasant. Evidently Russia has not progressed far beyond the status of those earlier days. She has escaped from the autocrat into the arms of the idiotocrat whose name is legion. How can the message of sympathy for the peasant, whom we would rescue from the Bolshevik, be delivered? He threw down his arms because the agents of Germany that had seized the tangled reins at Petrograd used their most efficacious weapon by spreading the rumor of lands that were being subdivided. To each soldier's heart came the impulse to rush and get his share. Thus was the work of Germany accomplished: she knew the spot on the Russian body-politic where the linden leaf had fallen. It is for us to find how to withstand successfully the murderous hosts of Hagen. We know that Hindenburg has appreciated, better than Ludendorff and the obstinate Crown Prince, the importance of the East. He is what is called an 'Easterner' in his attitude toward the strategy of the War; likewise there are 'Easterners' in England and France, who believe that as soon as the German offensive in the West has become a demonstrated failure, the influence of Hindenburg will be seen again in a stronger thrust by military, political, and commercial penetration into Russia and southward. Meanwhile the British forces in Mesopotamia are being strengthened by nearly half a million men from India, and as these approach the North and break into the Caucasus the message of deliverance will be borne to the confused and suffering peasant of Russia. As soon as he sees the hand of protecting government again in the place of the robber and murderer he will recognize and respond to the message of true democracy.

Another Mexican Taunt

Washington newspaper correspondents represent the Administration as being startled by the action of Carranza in severing diplomatic relations with the government of Cuba. This evidently is a mis-statement, for the Department of State possesses accurate information concerning the pro-German attitude of Mexico, and is aware of the activity of the Teutonic agents, which have brought stranger things to pass than this. The patience of the Administration is becoming sorely strained, as was shown by Secretary McAdoo's remarks at El Paso a few weeks ago. The friction with Cuba was a convenient excuse to flaunt before the Latin-American republics the peculiar views of the 'First Chief.' Despite the urging of his envoys to the Argentine, he sees that country, under the leadership of President Irigoyen, recognizing the material advantage of maintaining cordial diplomatic and commercial relations with the United States; he observes Peru following the example of Argentine in strengthen-

ing the ties of pan-American fraternity by establishing a \$20,000,000 gold credit with our Federal Reserve Bank: he has been disappointed in the failure of the president of Costa Rica to display resentment because his government was not recognized by President Wilson, for that enterprising little republic has become another champion of civilization by declaring war on Germany and thus manfully falling into line alongside of Uncle Sam. Accordingly Carranza takes advantage of a technicality to protest against a custom-house examination to which one of his special agents was subjected on his way from the Argentine, and he chooses to do it in a spectacular manner. Minister Candido Aguilar, speaking for Mexico, utilizes the incident to remind all Latin America that Cuba is a protectorate, and he hints darkly at the time when he may restore diplomatic relations between Cuba and Mexico on terms of "equality." In other words, the German is thus subtly indicated as a deliverer of oppressed nations, and our benevolent sponsorship for an autonomous Cuba, kept free from the fear of invasion, domestic strife, and ruin, is given the color of imperialism. The announcement in the dispatches that Spain has been the tool of Germany in stirring Mexico to this action is not credible. Everyone knows that Spain, as the mother country, is earnestly seeking to draw closer the bonds of sympathy between herself and her former colonies. To this no possible objection can be offered, and a precedent for it is found in the rapprochement of the English-speaking countries. We do not have to go far afield to discover the influences at work in Mexico. Practically all foreign houses have been driven out of business in the Mexican republic, with the exception of those controlled by the Germans. This has left the field open to them, and out of the profits accruing from exploiting the country they have expanded their operations until they have grown dominant in all branches of industry. Their financial strength has increased their usefulness to the government in its antagonism to American and British interests. Official favor has gone so far as to exempt firms that appear on our black-list from payment of the full amount of taxes due. These discredited firms continue to conduct business with the United States through other concerns, which so far have escaped the ban. Our tolerance has been great, but we cannot long permit the Enemy to use a neighbor as a base for his machinations against us. No quarrel exists between Mexico and the United States. We have done all that we could to re-establish a safe, dependable, democratic government south of the Rio Grande, and we would have succeeded but for the active propaganda of the Germans. A nation may repudiate our friendship if it so desires, but we are now at war, and we cannot suffer anyone to perpetrate acts inimical to our cause. The war we are waging is for the welfare of all mankind, for the weak as well as the strong, for Mexico as well as the United States. One of its results will be to preserve Mexico from absorption by Germany, and to ensure her freedom and autonomy. Every thoughtful Mexican must realize that fact, and must deplore the attitude of individuals that would keep us from establishing friendly relations.

A Professional Blunder

We hope every mining engineer that sees these opening lines will take the trouble to read this editorial to the end because it deals with a matter of vital importance to the profession. The statement of the case cannot be made brief because it covers a wide range in time and thought. It appears to us that an irretrievable mistake has been made, not by one engineer nor even by several, but by such part of the mining profession as has been connected with the big operations at Johannesburg. That mistake was the persistent ignoring of the inevitable impoverishment of the ore in depth. The economic collapse of several of the big consolidations of mining property on the Rand affords a reason for drawing attention to the blunder at this time. The pitiful plight of the East Rand Proprietary as a supposed 'investment' is indicated by the fact that the shares are selling now for 5 shillings as against 115s. in 1911. The American reader must excuse the use of British units of value, as they are always employed by those—European or American—interested in South African mines. As the East Rand Proprietary company has an issued capital of 2,445,897 shares of £1 each, the drop of 110s. per share represents a market-loss of £13,452,423, equivalent to \$65,244,251. In 1909 the yield of the East Rand Proprietary was 29.2s. per ton, on 1,830,280 tons, at a cost of 15.5s. per ton, leaving a profit of 13.7s. per ton. For the year 1916 the yield averaged 24s. on 1,939,200 tons, the cost was 19s., and the profit 5s. per ton. It must be understood, however, that the so-called profit is one of the fictions of Rand financial custom, the real profit for 1916 being £182,963, which is the difference between the balance brought forward from 1915 and the cash available for dividends at the end of 1916. This is equivalent to slightly less than 2s. per ton. The phantom profits of the South African mines have long been an absurdity, if not a scandal, the incorrectness of them being due to the fact that they represent an 'operating' profit, from which taxes, London expenses, interest on debentures, and other expenditures have to be deducted. The quarterly report for September 1917 contained "the melancholy information that development is to be curtailed and confined entirely to the more favorable areas," so says the 'Mining Magazine.' In plain English, the mine is sick unto death. In 1910 the East Rand Proprietary was estimated officially to have a life of 30 years. Another big consolidation, acclaimed a few years ago as a gilt-edged investment but now depreciated to the status of an insecure speculation, is the Crown Mines, the shares of which have fallen to 40s. from 190s. in 1910, the difference of 150s. on 1,880,212 shares representing a market-loss of £17,862,014, or \$86,630,767. The report for 1916 shows a yield of 25s. on 2,266,000 tons, a cost of 18s., and a profit of 7s. per ton, as compared with a yield of 35s. on 1,618,500 tons, a cost of 19.33, and a profit of 15.66s. per ton in 1911. In this case also the supposititious profit of 7s. must be reduced to 4.23s. per ton. The camoufleurant

cost-statements of these South African companies are so aberrant that the dividends distributed by the entire region usually represent only 65 to 70% of the nominal profit recorded in the statistics of the Chamber of Mines. In 1910 the Crown Mines was supposed to have a life of 50 years. Besides the East Rand Proprietary and the Crown Mines, we may mention the Rand Mines as another consolidation of the supposed 'consols' type. This last is a holding company, owning large blocks of shares in a number of representative mines, so that the quotation of Rand Mines served as a barometer of Rand prosperity. In 1911 this stock was quoted at 175s. per share, now it stands at 60s., the drop of 115s. on 1,866,661 shares representing a market loss of £10,733,318, or \$52,056,592. Thus these three consolidations, in less than seven years, have lost £42,047,755, or \$203,931,610, in market-value. A number of other mining companies, appraised as safe investments, have suffered like depreciation. The loss to the public, in England, France, and Germany, has been colossal. But the less informed reader will say that this is the fate of mining enterprises; they do not last forever; a mine is essentially a wasting asset; it has its periods of development, production, and exhaustion. That is true, but it was claimed insistently by the mining engineers on the Rand—American and English—that the seams of gold-bearing conglomerate constituting the ore deposits of the Rand were unlike the ordinary type of vein, they were like beds of coal, they maintained their gold content as long as they persisted, and of such structural persistence there was absolute geologic proof. The mining engineers of the Rand were wrong, and most of them knew it, but they allowed the financiers and promoters—the 'big houses' as they were called—to use a fallacious argument for the furtherance of schemes the ultimate purpose of which was to transfer the money of the public into the pockets of a few financiers and promoters.

Let us take the East Rand Proprietary as an example. In 1907 Mr. Frederick Hellmann, then general manager for this company, testified before the Mining Industry Commission that a decrease in the grade of the ore was "most marked" in "all mines" with which he was acquainted on the Rand. He added that impoverishment was especially noteworthy in the Driefontein, one of the East Rand Proprietary group. This testimony was not published in such a way as to be read by the public, although known to the leaders of the industry at Johannesburg. Nevertheless, in March 1910, at a general meeting of the East Rand Proprietary company, Sir George Farrar and Sir Lionel Phillips, two successful promoters that had won knighthoods in the usual way, testified as directors to the shareholders that the Angelo Deep, another mine of the group, had "added to the evidence that the Witwatersrand series was not decreasing in value" in depth, and that "if they excluded the surface area down to 200 or 300 feet, there seemed to be no evidence whatever that the gold contents at the deepest levels were not fully as high as they were at the surface,

or within 300 feet of the actual surface." Every well-informed mining engineer at Johannesburg and in London must have known this assertion to be false, but it passed unchallenged. We can go farther back. As early as 1903 Mr. Hennen Jennings, consulting engineer to the chief mining house, the firm of Wernher, Beit & Co., who controlled the Rand Mines company and many others, advised his clients that the evidence warranted increasing caution in commitments for deep development. His view of the matter was deemed so serious as to cause his firm to engage Mr. Ross E. Browne to come from California to South Africa, nominally to suggest new methods of mining, but actually to investigate the question of impoverishment in depth. His opinion, we understand, corroborated the cautious discernment of Mr. Jennings. Again the public and the shareholders were kept in the dark. In May 1903—15 years ago—the present writer, then editor of the 'Engineering and Mining Journal,' ridiculed the projects for tapping the Main Reef series at a vertical depth of 8000 feet, equivalent to 18,000 feet on the dip, and protested against the confident anticipation, in disregard of world-wide experience, that the 'banket' would continue highly profitable to an indefinite depth. That editorial was entitled 'Even Methuselah Died'; it suggested forcibly the mortality of mines as of men. It is evident now that the years of the Central Rand are numbered, for the latest projects for expansive development are being concentrated on the Far East Rand, where the Modderfonteins, the Brakpan, Springs, and other young mines give promise of generous productivity. It is noteworthy that in this part of the Witwatersrand the dip of the Main Reef Series is so flat that a point 14,000 feet on the dip is only 3000 feet vertically below the surface. Similarly, the two rich mines at Grass Valley, California, have been developed to 6300 feet on the dip, but the workings are only 2500 feet vertically. The suggestion is that the persistence of ore is related to depth below the surface, not to distance along the dip.

The rise in share-values was allowed to proceed, the absolute safety of the gold-mining 'investments' of the Rand was a theme of enthusiastic editorials in the subsidized financial press, and 'widows and orphans' were invited to place their savings in the big consolidations that were formed ostensibly to afford a wider foundation of industrial security, but really to enable the 'big houses' to disguise sundry failures and to merge numerous poor areas owned by them with the richer parts of the ore-bearing ground. In June 1911 the 'Times' said: "The question of the lodes giving out, which is the bogey of most mining concerns, does not exist for the Witwatersrand, for, though the ore of the reef varies in value, there is no doubt that it exists in payable grades and in large quantities down to any depth at which it may be practicable to mine it." This statement was promptly contradicted by the present writer as editor of the 'Mining Magazine'; it is a specimen of the piffle that the non-technical press has published in complacent subservience to the financiers. In the course of time the mining

engineers of the Rand had bemused themselves with the idea of indefinite richness, or 'payability'—to quote the local terminology—until some of them even believed it. In the late boom of the consolidation era, about 1910, they even talked themselves into the belief that as the mines became deeper they could be operated more cheaply, so that it became not uncommon for the statement of ore-reserves to include millions of tons of 'unpayable ore' assaying two or three pennyweights, at a time when even the pseudo-cost was twice as great. Thus the East Rand Proprietary in its report for 1909 itemized, among its resources, 2,593,643 (note the meticulous precision) tons of 'unpayable ore' assaying 2.4 dwts., equivalent to a mill-yield of less than 8 shillings per ton. To the shareholder this implied the expectation that some day, somehow, this rock would become an asset from which dividends might be squeezed. It was humbug, but the profession in London and Johannesburg winked at it. They were wilfully blind to two axioms of experience: the impoverishment of ore in depth and the concomitant increase of cost with depth once the economic scale of operations has been reached.

Not only did the engineers of the Rand shut their eyes to the testimony of experience the world over, but they even denied the truth when it was asserted. On May 31, 1911, Mr. C. O. Schmitt read a paper before the Institution of Mining and Metallurgy on 'Future Economies in Rand Reduction Plants,' in the course of which he predicted a diminishing profit in depth, much to the annoyance of the sensitive-plants that flourish in the hot air of the share-market. He was flatly contradicted by Mr. H. F. Marriott, the successor of Mr. Jennings as consulting engineer to the Wernher-Beit control. At this meeting of the Institution Mr. Marriott stated, concerning the grade of the ore: "There is no substantial evidence to-day, even for the most confirmed pessimist, to prove a general deterioration. My opinion in this respect is not merely advanced as a benevolent idea, but is based on the most complete evidence it is possible to secure, that of the assay-values of samples of actual reef-widths taken throughout all the mines and correlated." He was challenged by the present writer to bring forward his evidence, but declined to do so, until in December 1914, at a meeting of the Institution, during the discussion of the present writer's paper on the 'Persistence of Ore in Depth' he exhibited a stope-diagram "as material evidence," so he said, "against the views of those who claim that the Rand is one of the instances of decrease in value in depth." On that diagram the richness of the ore was indicated by tints, the dividing line between high-grade and low-grade being an assay-value the amount of which he would not specify. This evidence was misleading because the dividing line was far below even the average grade of the ore produced for many years by several outcrop mines of this group. That such information should be regarded as secret, that it should be considered the peculiar perquisite of the controlling house, not to be divulged to the shareholders at whose expense it was col-

lected, is in itself significant. On another occasion (in November 1914) the present writer was privileged to see a longitudinal section showing the stopes, $2\frac{1}{2}$ miles long, of the East Rand Proprietary. On this map the ground worked out was colored blue; the rich, the moderately profitable, and the unprofitable ground were indicated by variant tints. It was a graphic presentation of the life of the mine. Mr. Marriott pointed to it as proof of his denial of impoverishment in the deepest workings. The writer looked at it carefully and weighed the evidence, coming to the conclusion, which he stated frankly: (1) that, including the 300 feet of oxidized ground, he would rather have the gold in the first 1000 feet in depth than the gold in the next 2000 feet, and (2) he would rather have the gold in the first 3000 feet than that to be won from that point to the barysphere. The truth was told by evidence in the possession of the technical staff, but they had shut their eyes to it, so that they failed to see it. The present condition of the East Rand Proprietary renders further comment superfluous. Mr. Hellmann's frank testimony has been quoted. Mr. H. H. Webb also was one of the few to recognize the logic of events, even if his acknowledgment was belated. In the report of the Consolidated Gold Fields of South Africa, issued in 1913, Mr. Webb stated: "There can be no doubt that, from our experience and in our mines, the average value of the ore developed over large areas has been getting lower as great depth is attained." This official acknowledgment of a fact known many years earlier to any observant engineer on the Rand was received by the officials of the other financial houses as a misfortune to which their mines were superciliously superior. In the public discussion of this question technical opinion was muted, whereas the loud pedal was placed on financial optimism. The mining engineers of London and Johannesburg could offer no constructive suggestion to overcome the impoverishment of the ore in depth, so they fell over each other in advocating the idea of consolidation, which served to postpone the day of reckoning. That day has come, and it is with no sort of pleasure that we must record the fact that the profession has proved wanting in courage and sagacity. It has allowed reckless promoters and predatory financiers, now titled millionaires, to milk the public; it has been false to science and subservient to chicanery. It was not necessary to be disloyal to one's particular employer or to depreciate the market-value of the particular mine with which one was connected professionally. A paper before a technical society, a letter in a responsible journal, a cautious speech at a company meeting, warning the public that as surely as all men are mortal so eventually all mines must peter out—some pronouncement of a general character—would have sufficed, if made by any two or three of the leading engineers of the Rand. That would have checked the foolish expectations of the ignorant and handicapped the clever deceptions of the too cunning. Instead, the mining engineers of the Rand allowed the public to be victimized. It was not only wrong; it was stupid.

Even Methuselah Died

[An editorial by T. A. RICKARD that appeared in the Engineering & Mining Journal of May 2, 1903.]

We have published a series of contributions to the discussion of the problems arising from the proposed sinking of shafts to cut the Main Reef series on the Witwatersrand at depths of from 5000 to 8000 ft. While this discussion has covered the main questions connected with mining explorations to be carried out at levels deeper than any as yet attained by modern engineering, all those who have taken part in the debate have been strangely silent in regard to one feature, which, from the point of view of an onlooker at New York, seems vital, namely, will the ore at these great depths prove rich enough to warrant the tremendous expenditure entailed by the shafts and equipment thus contemplated?

In his excellent book on the 'Deep Levels,' Mr. G. A. Denny, who, by the way, also avoids the awkward question of values at great depths, gives data which warrant an estimate of a million dollars, as the cost of the sinking and equipment of a shaft to a depth of 5000 ft. It is safe to say that shafts approaching 8000 ft. in profundity will cost fully two million dollars. Even this amount, however, is not overwhelming, by any means—having regard to the scale of operations contemplated—provided that the ore continues as profitable as it has been from the surface to, say, 1500 ft. measured vertically.

Our readers are aware that the proprietary owning claims which cover the croppings of a reef is called an 'outcrop company.' As the South African laws do not recognize extra-lateral rights, and the reef dips southward, the outcrop company can only follow the ore to a certain line vertically underneath its southern boundary. Beyond that line the dip carries the ore into adjoining property—the first 'deep-level.' In turn, the latter's rights cease southward as the dip carries the reef into the next property, the 'second row' of deep-level mines. And so on. The outcrop mines were, of course, the first to start operations; since then work has been begun on the first row of deep-levels; in many instances the second row is now being exploited, while, finally, in two or three cases even the third row has been tapped, the distance from the outcrop, and the consequent depth of sinking, varying according to the location of the claims. To this it may be added that as the consolidation of claims makes blocks of ground of irregular shape, the distance from the outcrop of the successive deep-level shafts varies between wide limits.

Of the results to date it is only necessary to say that the outcrop companies and the first row of deep-levels have demonstrated the Main Reef series to be the most wonderfully uniform gold lode ever mined by man. But several of the deeper mines have proved disappointing to an extent sufficient to emphasize the fact that while the

'banket' may be as uniform as a coal-seam, even a coal-seam will eventually pass into shale of little value as fuel.

The producing deep-level mines tabulated by Mr. Denny have vertical shafts ranging from 615 to 1608 ft., the average being about 1100 ft. These are 'deep' only in technical phraseology, because they occupy territory on the underlie of the reefs, the upper parts of which are owned by 'outcrop' companies. Returns obtained up to date from actual milling operations are manifestly of little value in forecasting the results to be expected at depths of 5000 to 8000 ft. In the calculation of probabilities 1100 ft. is to 8000 ft. as the vision of the unaided eye is to a telescope. The fact is, the term 'deep-level mine,' which at Johannesburg is used in distinction to 'outcrop mine,' has a misleading sound, and does not at all necessarily imply deep mining in the ordinary sense. It is doubtful if this is appreciated sufficiently.

However, there is other evidence. Eleven bore-holes have been put down to depths of over 2000 ft. Two of these—the Turf Club holes—cut the Main Reef series at 4825 and 4845 ft., respectively, with results ranging from 6 to 10 dwt. per ton, and widths of 34 to 45 inches. The working cost at twelve of the so-called 'deep-levels' averages $6\frac{1}{2}$ dwt. But this does not allow for losses in treatment. A yield of $6\frac{1}{2}$ dwt. per ton is equivalent to gold contents of slightly over 8 dwt., which then is the amount to be deducted from the assay in order to arrive at the profits. Therefore, having regard to the much greater depth and consequent larger expenditure in equipment, an ore carrying between 6 and 10 dwt. at 5000 ft., does not represent much profit, if any. But it warrants a certain amount of exploration.

The data obtained from the two deepest holes have been quoted. The others have given varying results. At 3309 ft. the Cinderella bore cut, in February of the current year [1903], a body of banket having with partings, an aggregate thickness of $16\frac{1}{2}$ ft. Only 4 ft. of this was of payable grade, and the 4 ft. averaged 9.16 dwt. Another bore-hole, also over 2000 ft. in depth, cut 36 in. of banket at 2960 ft. This averaged 8 dwt. A fifth gave 14 in. of 17-dwt. ore, which is equivalent to a stoping width of about 6 dwt. Three other holes gave very low assays, and the remaining three reaching below 2000 ft., penetrated into disturbed ground, failing to cut any reef. While those last mentioned did not give direct evidence of poverty, they indicated that the irregularities of structure encountered in the upper levels will recur in depth—where, however, they will become a much more serious factor.

Of course, drill-holes are proverbially dangerous. Indeed, one might almost say that drill-holes have a depressing habit of going through the poorest places in a

lode or vein. Nevertheless, in default of other evidence, their testimony must be heeded. In so far as they throw light on the future of deep mining on the Rand, they hold forth no brilliant promise: the ore cut by them, even in the six fortunate holes, averages, for a stopping width of 4 ft., about 8 dwt., which is equivalent to an extraction of $6\frac{1}{2}$ dwt. per ton.

However, to us there seems to be a much stronger reason for scepticism concerning the uninterrupted persistence of pay-ore, ore capable of yielding a good margin of profit, to such tremendous depths as those contemplated in the discussion on winding plants [by H. C. Behr and others]. A vertical depth of 8000 ft. means a distance from the outcrop, as measured on the average dip (26°) of the reef, of over 18,000 feet.

All the experience of mining is dead against the supposition of a maintenance of values over any such extraordinary range of lode-surface. Mines get poor, sooner or later, just as surely as men grow old. Even Methuselah died. It is a fact that the most persistent metal-bearing veins in the world, namely, those of the Lake Superior copper region—built up of conglomerate also, like the Rand blanket—have at last begun to show signs of a change in character and a concomitant impoverishment. These mines have attained a vertical depth of a little over 5000 ft., equivalent to 8000 ft. from surface as measured on the vein. Of other deep mines, on the Comstock, at Bendigo, etc., it is needless to speak. Let the unthinking repeat the old fable that mines become richer in depth, but knowledgeable engineers do not need to be lectured on that point. Is not this brutal fact being evaded by the professional men who are directing the work on the Rand?

This important subject is broached with no desire to underrate the resources of the great Main Reef series. We appreciate fully the fact that never has gold mining been placed on so sound a basis as at Johannesburg, and we recognize that only those who have had a wide experience can really understand the difference between the hazards of an ordinary mining venture and the safe investment furnished by the established producing mines of the outcrop and first row 'deeps' of the Rand. There never were mining enterprises which assured so certain a return of capital and interest. But has not the inference, as regards future operations at six or eight thousand feet, been over-drawn, and is it not time to face the facts, in particular, as presented on the Rand, and in general, as furnished by other regions, and recognize that the rim of the synclinal basin affords better prospective chances than the long shots at the great depths contemplated in the discussion to which we have made reference?

TIN recovered on the Dutch islands of Banka and Billiton is not all alluvial, as popularly supposed. Lodes are now being worked. One mine is 350 ft. deep, with 6000 ft. of openings. Cassiterite and wolfram— $2\frac{1}{2}\%$ Sn and 1% WO_3 —are found disseminated in greisen (quartz and mica). Two mills treat 200 tons of ore daily.

The Lambert Conformal Conic Projection

The Department of Commerce announces the publication by the United States Coast and Geodetic Survey of Serial No. 77, Special Publication No. 47, 'A Manual on Lambert's Conformal Conic Projections, with Two Standard Parallels,' by C. H. Deetz. This is the projection of the official map of France and is used in the war zone for the new battle-maps, displacing the Bonne system of projection heretofore employed by that country. The manual is issued in response to calls for information on the subject from several departments of the Government, as well as from outside sources. It comprises about 61 pages, illustrated by 14 figures and 7 descriptive plates. Besides a description of the projection, the mathematical development of its formulas, and the French system of kilometric squares in topographic mapping, there is included a comparison of the Lambert with the Boone and with polyconic systems of projection. Copies of the publication may be obtained at 75c. each from the Superintendent of Documents, Government Printing Office, Washington, D. C.

The Lambert projection offers advantages in the mapping of countries of predominating east-and-west dimensions. Its meridians being straight lines, and its parallels arcs of concentric circles, the projection is well adapted to indefinite east-and-west extension, a property belonging to this general class of single-cone projections, but not found in the polyconic where adjacent sheets have a 'rolling fit' because the meridians are curved in opposite directions. For a map of the United States, the maximum error in scale is reduced from $6\frac{1}{2}\%$ in the polyconic to $1\frac{1}{2}\%$ in the Lambert projection. The merits and defects of these two systems of projection are in opposite directions. A study of the shapes and extent of any areas to be mapped, therefore, is the deciding factor in the choice of a projection to meet the requirements that a map is to fulfill.

ALUMINUM alloys have been known to enter largely into the construction of zeppelins. Recently the 'Iron Age' obtained a piece of the metal from one of these German airships and had it analyzed. The composition proved to be:

	%
Aluminum	91.92
Copper	4.13
Iron	3.27
Silicon	0.65

The alloy had been rolled, and showed a tensile strength of over 40,000 lb. per square inch. It is assumed that the copper was introduced into the mixture in the form of silicon-copper.

TIN OUTPUT of Malaysia in 1917 amounted to 19,752 tons of metal, a decrease of 1974 tons compared with 1916.

Mining in the Lower Copper River Basin

By F. H. MOFFIT

*The Kennecott-Bonanza mine shipped its first ore early in 1911. Since then the Jumbo mine has been opened, and exploratory work has been started on the Erie claim. These properties all lie within three miles of one another, along the contact of the Nikolai greenstone with the Chitistone limestone on the east side of Kennecott glacier. They belong to the Kennecott Copper Corporation.

During the five years since 1911 a large quantity of high-grade copper ore has been shipped to the smelter from the Bonanza and Jumbo mines, and the mines them-

man for a great deal of information which a geologist who has not been closely associated with the work of exploration cannot get readily, if at all.

THE BONANZA MINE is in the mountains between Kennecott glacier and McCarthy creek, at an elevation of 6000 ft. The Jumbo mine is nearly a mile north-west of the Bonanza and a few hundred feet lower. The main tunnel of the Erie is $1\frac{1}{2}$ miles still farther north-west, at an elevation of 4325 ft. and within half a mile of the Kennecott glacier.

The copper deposits of the Bonanza, the Jumbo, and the Erie resemble one another in the character of the ores and in the fact that they occur in the limestone only a short distance above the greenstone. It is therefore probable that they were formed at the same time and under the same conditions.

FIG. 1. FAULTING IN THE BONANZA MINE

selves have been opened so as to expose the copper deposits and give a much more accurate idea of their extent and character than could be gained at the time when they were examined by S. R. Capps and the writer.¹ For this reason it seems desirable to describe these deposits more fully than the other deposits in the district, especially as such a description may be helpful to anyone who may be studying other copper deposits in the limestone. The writer acknowledges his indebtedness to those in charge of the mines for placing at his disposal every means for studying the copper deposits and in particular to H. D. Smith, E. T. Stannard, and A. M. Bate-

FIG. 2. HORIZONTAL SECTION OF JUMBO OREBODY ON 500-FT. LEVEL

The Bonanza mine is on a sharp ridge that separates the heads of Bonanza and National creeks, tributaries of Kennecott glacier. The head of National creek is a glacial cirque; that of Bonanza creek is also a cirque with a precipitous wall on the east, next to the mine. This cirque is still occupied by a small glacier. The ridge trends N. 30° E. From the mine the ridge rises steeply northward to the divide between Bonanza and National creeks and the basin of McCarthy creek, but extends southward without much variation in elevation for half a mile and then drops off steeply toward Kennecott glacier. A trail up National creek leads to the mine.

The geologic features are simple. On the south is the Nikolai greenstone (Triassic?), a succession of ancient lava-flows at least 5000 ft. thick. It is overlain by the massive Chitistone limestone (Upper Triassic), but is

*Abstracted from 'Mining in the Lower Copper River Basin.' By F. H. Moffit. Bull. 662-C. U. S. G. S.

¹Moffit, F. H., and Capps, S. R., 'Geology and Mineral Resources of the Nizina District, Alaska,' U. S. Geol. Survey, Bull. 448, pp. 84-92, 1911.

separated from it by a thin bed of shale, which has a maximum thickness of only four feet and is easily overlooked except in favorable exposures, because the base of the limestone is commonly covered by debris from the cliffs above. A typical profile across the limestone-greenstone boundary shows steep cliffs of limestone above a moderate slope in the greenstone, although at many places the greenstone is hidden by loose material, or 'slide-rock,' as the prospectors usually call it.

The limestone between Kennicott glacier and McCarthy creek has a north-westerly strike and, in the vicinity of Bonanza mine, dips about 22° N.E. It is cut by numerous faults and fractures, some of which had a most important influence in directing the course of circulating waters and controlling the deposition of copper minerals. The faults comprise, among others, the two systems that had most to do with the formation of the deposits. One system is distinguished by fractures with steep dips and with approximately north-east strikes; the other by fractures with practically the same strike and dip as the limestone beds. Both fault-systems probably originated at about the same time. They are intersected by steeply dipping cross-faults, either of the same age as the major faults or possibly older, along which the copper-bearing solutions spread out for a short distance from the main fractures. They are also crossed by fractures that originated after the ore was deposited.

The ore-bearing faults and fissures of greatest importance among those just mentioned belong to a zone of fracture and faulting that extends N. 30° E. This zone is made up of steeply dipping faults and fractures that strike N. 30°-70° E. and that, together with the bedding-plane faults, were most effective in directing the flow of mineral-bearing waters.

The bedding plane or 'flat' faults indicate movement of one limestone bed on another or movement along a plane parallel or approximately parallel to the bedding. Such movement, however, was not restricted to planes of bedding, for in places the 'flat' faults are slightly wavy and cross limestone beds at a slight angle. Bedding-plane faults occur in the lower part of the Chitistone limestone at many places throughout Chitina valley, and at least four are recognized in the Bonanza mine. The contact of limestone and greenstone in particular was a place of movement, which was facilitated, no doubt, by the thin bed of shale at that place. Evidences of such movement are found in the shale at the Bonanza mine.

Two principal cross-faults are seen in the Bonanza mine, the Mammoth, which strikes N. 52° W. and dips 70° N., and the Azure, which strikes N. 62° W., dips high north, and is in reality a shear-zone about 100 ft. wide, made up of minor nearly parallel faults. The Mammoth fault produced a displacement of less than 20 ft. in the limestone and is older than the ore. The Azure fault is a normal fault that caused very little displacement. Movement has taken place along this fault since the ore was deposited, but the faulting may have begun earlier. Much of the limestone along the fault-zone is crushed. The direction of latest movement in the Azure

fault is indicated on slickensided surfaces by striae that dip 70° west.

Although the Mammoth and Azure faults are the most conspicuous of the cross-faults in the Bonanza mine, many other cross-faults having the same general strike cut the principal ore-bearing fissures. Some of them are manifestly later than the ore, for they offset it. Some of them carry small quantities of ore, as may be seen on the 400, 500, and 600-ft. levels. It appears not improbable that cross-faults were produced when the principal shear-zone was formed and that movement took place along some of the faults of both sets after the ore was deposited.

It is difficult to make more than qualitative statements in regard to the displacements produced by faulting except as to a few of them. The vertical displacement along steeply dipping faults is slight. Some of the movement, particularly along faults that run north and south, was nearly horizontal, or parallel to the direction of the present dip. The displacement in this direction is small, but greater than that in the direction perpendicular to the bedding-planes. Displacement along the bedding-planes is difficult to measure because reference points are lacking, but in some places not far distant from Bonanza and Jumbo mines it is considerable, amounting to hundreds of feet.

Close examination of the rocks adjacent to the contact between the Chitistone limestone and the Nikolai greenstone at the Bonanza mine disclosed the following section:

Section at Bonanza Mine

Limestone, magnesian, granular, ore-bearing.	
Fault; in places forms contact between magnesian and non-magnesian limestone.	Feet
Limestone, dark gray, non-magnetic.	50-60
Limestone, silicious, containing a little pyrite.	20
Shale, red or green.	4
Greenstone, amygdaloidal (Nikolai).	

The first large orebodies found were in the magnesian limestone, so that at one time it was supposed that this rock had controlled ore deposition, and exploratory work was conducted accordingly. As the work proceeded, however, this supposition had to be given up, for the ore was found in both the magnesian and the non-magnesian limestone. At some places a fault approximately parallel to the bedding-planes separates the magnesian and non-magnesian limestones, but at others the contact of the two is defined neither by a fault nor by a bedding-plane, but crosses the bedding irregularly.

The list of copper minerals in the ores of the Kennecott-Bonanza, formerly thought to include only chalcocite, covellite, and copper carbonates, has been extended as underground work proceeded and now includes chalcocite, covellite, azurite, malachite, enargite, bornite, chalcopyrite, bluestone or chalcantinite, and possibly other minerals. The ore is dominantly chalcocite. Covellite, like azurite and malachite, is common and, at least in some places, seems to be a product of the alteration of chalcocite. It forms veinlets that cut the chalcocite and it coats with tiny crystals the surfaces of open spaces in the chalcocite. Enargite is rare but is found in the

150-ft. and 300-ft. levels. Bornite is found throughout the mine and chalcopryite in the lower levels, though it is uncommon.

The ore occurs as great tabular replacements of limestone along 'vertical' faults, as tabular replacements along 'flat' faults, as irregular masses, as networks in brecciated limestone veined with calcite, and as veins that have replaced limestone along bedding-planes and that are in places only a few inches apart.

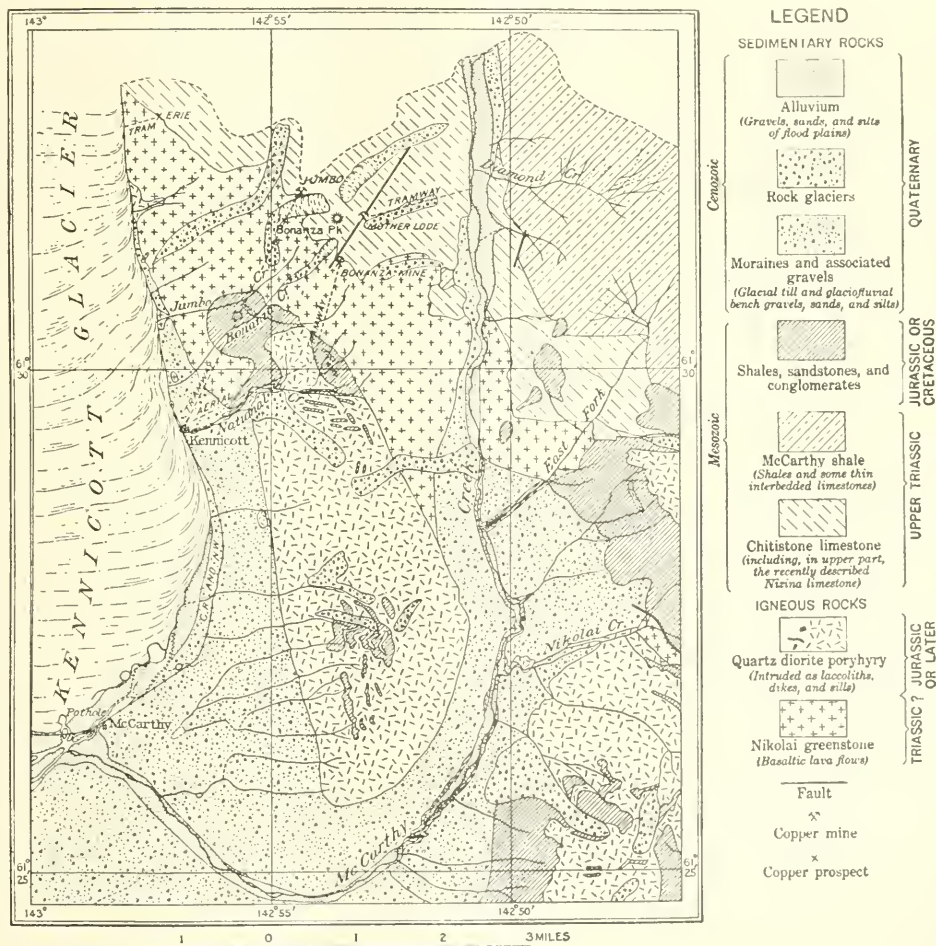

The great orebodies belong primarily to the 'vertical' fault-system and have been found at the intersection of the 'vertical' with the 'flat' faults. They lie above the flat fault and terminate sharply against the underlying limestone, yet copper ore is found along vertical fissures below the flat faults at some places, as in the 'little bonanza' open-cut at the south end of the orebody. The little bonanza is a mass of chalcocite, covellite, copper

carbonates, and chalcantinite in vertical fissures of the main fault-system, which lies on the west side of the ridge and extends down to the shale. It was not exposed to view until the talus material had been cleared away.

The largest orebodies so far uncovered were found at the south end of the mine. They followed fissures striking N. 50°-70° E. and were adjoined on the north by smaller bodies striking about N. 30° E. The formation of the larger deposits was much influenced by the Mammoth fault, for, although the limestone beds were not greatly displaced by the fault, the copper-bearing solutions spread out along it and produced local enlargements of the orebodies. South of the fault the ore reached a width of about 80 ft., but a short distance north of it the width was much reduced. The Mammoth fault appears only in the upper levels, for it crosses the south end of the orebody and reaches the north-eastward dipping

U. S. GEOLOGICAL SURVEY

BULLETIN 652 PLATE XI

surface of the greenstone between the 200 and 300-ft. levels.

The 'vertical' bodies of the higher levels had a high westerly dip, which increased in steepness as the ore was followed in depth toward the north-east. Ore was mined in the main fissure-system to a width of 85 feet.

The ore is cut by faults that show little displacement, at least not much is shown by the steeply dipping faults. The Azure fault is over 800 ft. north-east of the Mammoth fault. It appears in the 300 to 600-ft. levels and meets the greenstone between the 600 and 700-ft. levels. Movement took place in it after the ore was formed. Three other principal vertical north-south faults offset the orebodies, as is evident at the surface and in the 100-ft. level of the mine. Such faulting as that indicated in Fig. 1, however, apparently took place before the ore was deposited and offset the two earlier faults, which the ore-bearing solutions followed later.

The north-south fault caused displacement chiefly in a horizontal direction. One of the striking features of the ore deposits is the sharpness with which they are limited by some of the fault-planes. In many places a thin gouge, scarcely thicker than a sheet of paper, has been sufficient to prevent the solutions from reaching the limestone on one side of the fracture while that on the other was being entirely replaced. The gouge along the fault-planes is locally highly colored with iron oxide.

The exposures at the surface of the Bonanza mine show no more oxidized ore than those in some of the lower levels. Oxidized ore continues to the lowest (700-ft.) level and is evidently most abundant where the ore was faulted and crushed and where water could therefore circulate freely. Oxidation is at some places confined to one side of a tight fault. Locally the chalcocite is brecciated and much oxidized, showing kernels of original chalcocite in oxidized ore. The Bonanza at present is a dry mine.

The workings have now reached the 700-ft. level. The adit is the 150-ft. level. From that level an incline runs nearly parallel to the contact of limestone and greenstone and descends to the 600-ft. level. From the incline, in turn, levels are driven off north-eastward into the orebody. A winze has been driven from the 600-ft. level to the 700-ft. level. The 300-ft. level connects by a short raise with the McCarthy creek side of the ridge. Much high-grade ore, including most of that exposed originally at the surface, has been mined above the adit-level, through which it has been drawn off. In this mine thorough exploration is necessary to trace the ore; all small veins and stringers must be closely followed, for many of them develop into valuable bodies of ore within short distances.

JUMBO MINE. The copper deposits of this mine resemble in most respects those of the Bonanza. The mine is in the Chitstone limestone, near the head of Jumbo creek, just above the contact of the Chitstone with the underlying greenstone. Jumbo creek originates in a small glacier on the west side of Bonanza Peak and flows south-westward to Kennicott glacier, which it joins 1½

miles north of Kennicott. The glacier is confined on the north and east and for some distance on the south by precipitous cliffs of limestone. The Jumbo mine is in the north wall of this cirque, nearly half a mile from the head of the glacier. All the mine-buildings are set on the glacier.

The geology of the mine is practically the same as that of the Bonanza. A stratigraphic section shows greenstone at the base overlain by two feet of shale. Then come, in ascending order, about 20 ft. of silicious limestone containing a little pyrite, 50 to 60 ft. of dark-gray limestone, and finally granular magnesian limestone. In the adit or 180-ft. level of the mine the limestone beds strike N. 50° W. and dip 34° N. The dip is therefore a little greater than at the Bonanza and the strike is a little more westerly. A short distance east of the entrance of the 100-ft. level of the Jumbo a light-colored porphyritic dike two feet thick intrudes the limestone. It has not yet been encountered underground.

A fault-zone whose general course is a little south of north-east cuts the limestone but displaces the beds very slightly. It comprises fissures and minor faults that range in strike from N. 60° E. to east and a few that strike about N. 30° E. This fault-zone is made up of the principal ore-bearing fissures. Near the outcrop of the ore the dip of these fissures is 70°-80° W., but as the fissures are followed to the north-east the dips become steeper and in some of the faults are south-east.

The main fissure-zone is cut by cross-faults that trend north-northwest and by a few that trend north. At one locality the ore is displaced one foot by a fault that trends north and at another place two feet by a fault that trends north-northwest.

Of much more importance than these cross-faults are the bedding-plane or 'flat' faults. In the Jumbo mine, as in the Bonanza, the bed of shale between the limestone and the greenstone is evidently a plane of movement, for wherever the shale is exposed it is crushed to a thick gouge. The fault along the shale bed has apparently a much less significant relation to the copper deposits than the fault immediately below the rich orebodies. This fault is about 80 ft. above the greenstone and is in places made up of several closely spaced parallel faults. It does not strictly follow the bedding-planes but crosses the bedding at a slight angle, and on the 500-ft. level it strikes N. 70° W. and dips 35° N. It is cut by all the levels and marks the bases of the rich orebodies. Movement along this fault-plane after the ore was deposited is indicated on the 180-ft. level by a fault-breccia containing a little chalcocite. Although this post-mineral movement has taken place, the original displacement occurred before the ore was deposited.

The ore of Jumbo mine is prevailingly chalcocite, but includes a subordinate quantity of copper carbonates, as well as enargite, bornite, and chalcopyrite. In places covellite is associated with the chalcocite. According to H. D. Smith, in charge of the mining, if the proportion of chalcocite and carbonates that can be distinguished by the eye is estimated as 98%, then 1.9% will represent the

covellite and 0.1% the bornite and chalcopyrite. This estimate is, of course, only approximate, but it indicates the relative quantities of the copper minerals in the ore. The ore from the Jumbo mine shows more oxidation than that from the Bonanza. The carbonate ore consists generally of malachite and azurite, but that in certain stopes includes malachite alone. Silver occurs with the copper at the Jumbo mine as well as at the Bonanza. The proportion is slightly variable and ranges from 14 to 16 ounces per ton of high-grade ore. The silver content of chalcocite near fissures is less than that found at a distance from them, a fact demonstrated by careful assaying. The width of the ore-bearing ground worked is not less than 240 ft., yet the limits of the ore have not yet been reached.

In form the orebodies are like those of the Bonanza. The large tabular masses of chalcocite replace limestone along the north-easterly striking faults, but all openings in the fractured limestone along the fault-zone were invaded by the ore-bearing solutions so that stockworks and irregular orebodies are common.

Ore was deposited in great quantities at the intersection of the 'vertical' and bedding-plane faults between the 400 and 600-ft. levels. The 'vertical' faults here strike N. 65° E. and dip steeply to the north-west. The bedding-plane fault strikes N. 72° W. and dips 34° N. The great orebody was on the south-east side of the main 'vertical' fault and lay for the most part, but not entirely, above the bedding-plane fault, between it and the magnesian limestone. It extended from a point a short distance above the 600-ft. level to a point 30 ft. above the 400-ft. level. In projection on a horizontal plane it had a length of 400 ft. At its lower end was an open cave in the limestone, partly below and partly above the fault. A horizontal section of the orebody at the 500-ft. level is shown in Fig. 2.

This great mass of ore was practically solid chalcocite, with which was mixed an almost insignificant quantity of included limestone, largely altered to residual clay. It yielded 50,000 tons of copper ore, much of which ran 76% copper. This massive body of chalcocite was at the 500-ft. level, bounded on its lower side by a bedding-fault, but below this fault there was ore of lower grade which was terminated, 6 to 8 ft. lower, by a second fault parallel to the first, beneath which no ore was seen except a few tons at one place.

A map of the 500-ft. level shows, in addition to the orebody just described, two principal tabular orebodies along parallel 'vertical' fractures extending north-eastward and other irregular orebodies. On the 700-ft. level also there were two main fissures at the north-east extension of the drifts. The sharp clean-cut boundaries between limestone and chalcocite and the total absence of gangue-minerals except calcite are striking features of the ore deposits both here and at the Bonanza.

The main adit of the Jumbo mine is the 180-ft. level. This level penetrates between 200 and 300 ft. of greenstone before entering the limestone. From this level an incline with a slope of 33° to 34° descends to the 700-ft.

level, in which a shaft is being sunk. The incline was started with the expectation that it would penetrate barren ground away from the orebody, but it encountered much high-grade ore. Intermediate levels were driven to the north-east from the incline into the orebodies, just as they were at the Bonanza.

Federal Explosives Law

Under the new Federal Explosives Act approved by the President on October 6, 1917, and effective November 15, 1917, every person was required to have a license for the purchase, possession, sale, or use of explosives, or ingredients of explosives. Explosives are dynamites, blasting and shot-gun powders, caps, and many other commodities listed in the Act, as well as the component parts of these materials, which under the Act are classed as ingredients. The Bureau of Mines of the Interior Department is charged with the enforcement of this law. The Director of the Bureau of Mines has appointed Licensing Agents for the issuing of licenses in every hamlet, village, town, and city in the United States. In California we have over 700 licensors equipped and commissioned to issue licenses. The County Clerk of every county in California is appointed a licensor. In almost every instance Justices of the Peace are appointed licensors, as well as Notaries Public. To obtain a license an applicant must appear in person before the licensor; must state under oath his place of birth, if a naturalized citizen, must give the date and place of naturalization. Licenses will not be issued to enemy-aliens, or to subjects of a country allied with an enemy of the United States. Subjects of neutral countries are entitled to licenses if they are known to be loyal and responsible. Licensors are instructed to refuse to issue a license to any person not known to be loyal and responsible unless recommended by reputable citizens of the community. A person who has been refused a license by a licensor may appeal to the National Council of Defense at Washington. If the National Council of Defense grants the appeal it will make an order upon the Director of the Bureau of Mines to issue the license. The purpose of the Act is to prevent disloyal persons from procuring explosives, and to keep explosives out of the hands of persons who will not guard them carefully enough to prevent them from being stolen or used by disloyal persons.

PENALTY: Sec. 19. That any person violating any of the provisions of this Act, or any rules or regulations made thereunder, shall be guilty of a misdemeanor and shall be punished by a fine of not more than \$5000 or by imprisonment not more than one year or by both such fine and imprisonment.

Location of licensors, or other information regarding the Federal Explosives Act can be obtained by communicating with John M. Griffin, U. S. Explosives Inspector for California, Madera, California.

FUEL-OIL CONSUMED by United States railroads during 1917 amounted to 45,707,082 bbl., an increase of 8.5%. Oil-burning locomotives operated in 21 States.

Nitrate-Plants

By DAVID HOLT

*The United States government has made provision at Muscle Shoals for the production of 180,000 tons per annum of nitric acid by the cyanamid process. Though the completion of dam No. 2 will not give to Decatur, Huntsville, Chattanooga, and other up-river points the year-round navigation desired, recent changes in plans will provide a surplus of electric energy to be used by the Government for other enterprises, or for privately-owned industries. While rejoicing at the establishment of a cyanamid plant at Muscle Shoals that will cost the Government more than \$30,000,000, and the construction of dam No. 2 on a scale that will involve the expenditure of \$20,000,000, the advocates of Tennessee river improvement do not feel that their work is completed, but only that it is well begun. The dam as it appears when completed, together with the power-plants thereon, will be a monster monolith of concrete. There will be no necessity for later changes to increase the utilization of power. Practically the entire potential horse-power of the Tennessee river at that point will be brought into service.

The air-nitrates plant at Muscle Shoals, the larger of the two now under construction, will use the cyanamid process, and the smaller, situated between the cities of Sheffield and Tusculumbia, will use some modification of the Haber process, which has been successfully operated for several years in Germany. For the Haber-process plant, known to the Government as Plant No. 1, the requirements of electric energy and crude material are proportionately less than those of the cyanamid plant. At first Plant No. 1 was referred to as the 'experimental' plant, but now objection is made to the use of this designation. The men who are responsible for its construction say there is nothing experimental about it; that both the process and its application have been proved and demonstrated. They call it the 'synthetic ammonia' plant.

Still, the cyanamid process is the one in use at Niagara Falls, where, on the Canadian side, nitrate of ammonia, nitric acid, anhydrous ammonia, cyanides and case-hardening compounds, together with many other products, are now being manufactured in commercial quantities. Cheap electric power, abundant limestone and coke are essentials for the manufacture of cyanamid. An authorized statement gives the information that, by the cyanamid process, the air is first liquefied by intense cooling under high pressure, pure nitrogen is boiled off, which is absorbed in a white heat in a powdered mass of fused lime and coke. The pure nitrogen absorbed by the powdered calcium in a special oven forms cyanamid. It requires about one horse-power of continuous electric energy to produce two tons of cyanamid per year. By June 1 the synthetic plant, costing \$5,000,000, and occupying a 1700-acre site, is expected to be ready for manu-

Haber process for producing ammonia, nitric acid, and ammonium nitrate. No. 1 plant is situated at West Sheffield, on the south side of the Tennessee river, and is being built under Government contracts with the J. G. White Engineering Corporation of New York. The machinery is being installed by the General Chemical Co. of New York, which controls the Haber process and has donated it to the Government for military purposes. It will have a daily capacity of 30 tons of ammonium nitrate and 4 tons of nitric acid. No. 2 plant, for which \$30,000,000 is available, is being built at the new town of Muscle Shoals on the Government reservation adjoining Sheffield. Until the completion of the Muscle Shoals power development by the Government, electricity for the nitrate plants will be supplied from two steam-driven electric generating stations developing 60,000 hp., being built for the Government by the J. G. White Engineering Corporation, and from the big steam-driven electric plant which the Alabama Power Co. of Birmingham is building on the Warrior river at the mouth of a coal mine.

Consumption of Tin in the United States

According to a statement issued by the War Industries Board from returns obtained through the sub-committee on pig tin, the consumption for different purposes in this country during the calendar year 1917 was as follows, in long tons: tin andterne plate, 27,600 tons; solder, 17,000; babbitt and other bearing metals, 10,800; brass and bronze, 4800; foil, 4000; collapsible tubes, 2100; white metal, 1764; and miscellaneous, 8193; making a total of 76,257 tons.

The miscellaneous item has been subdivided as follows:

	Long tons
Galvanizing	105
Tinning and re-tinning.....	1916
Partly for tinning and re-tinning and partly for other uses	595
Bells (reports of 3 manufacturers making bells only)	15
Pipes (tubes), for organs and soda, beer, etc., fountains	276
Partly for pipes and partly for other uses.....	620
Rubber	126
Type metal (reports of 2 manufacturers making type metal only)	35
Bullets	65
Plated ware, britannia ware, etc.....	1002
Chemicals (oxide, bichloride, crystals, and tetrachloride and crystals)	1718
Not specified	900

As the United States is almost wholly dependent upon foreign sources for tin, it is of interest to note that importations of tin and tin ore during the first quarter of 1918, stated in terms of metal, have been at the rate of 5873 long tons per month or 70,476 tons per annum. To get an accurate estimate of our total supplies, however, the amount of tin recovered by detinning plants and in other ways should be added to these imports, as well as the almost negligible amount of tin produced in this country. Our exports of domestic and foreign tin, although small, should also be taken into consideration.

*Abstract: 'Manufacturers Record,' April 11, 1918.

fabricating nitrates for explosives under the modified

The Mining Industry: The Keystone of Modern Civilization

By R. H. STRETCH

It is perfectly feasible to demonstrate the truth of the above caption. In sculpture, poetry, oratory, philosophy, and kindred lines of mental development, it is generally admitted that we are no more than the equals of the Greeks and Romans in the palmy days of their art and literature. We differ from the men of those far-off days only in our mastery of the mineral resources of the earth and in our ability to make them subservient to the cause of science and, through science, to the more perfect and luxurious housing, clothing, and feeding of the human race. The advance has been along purely materialistic lines.

While mining began with a knowledge of the uses of copper, tin, and lead, many ores of which are easily reducible to the metallic form, the main impulse was imparted by the discovery of means to separate the more refractory iron from its matrix, and the manifold uses to which that metal could be put. The nations possessed of this art conquered the less fortunate races and changed the destiny of empires. It has widened the domains of poetry and music by mechanical improvements; by similar means it has made it possible to reproduce statuary in facsimile; it has enabled us to perfect instruments so as to supplement the knowledge of the Chaldean astronomers and unlock the secrets of the heavens; it has extended our knowledge of the earth, banishing the weird fancies and speculations of Aristotle and his co-workers in the infancy of science; it gave us the alchemists and their less empirical successors, who, while delving into the mysteries of nature by which they were surrounded, have made discoveries that have revolutionized our daily lives. Progress was slow, and it took centuries to batter down the stone walls that ignorance had erected around preconceived ideas and dogmas. Animal and human labor were the chief sources of power, and were handicapped by the difficulty of application where concentration on a large scale was a prerequisite to success. Being unable, in the early stages of discovery, extending over many centuries, to handle underground waters, explorations were necessarily confined to such mineral deposits as were found on the surface of the earth and could be drained of water by gravity only. No deep mining was possible. Sculpture might flourish and magnificent buildings might be erected out of brick and stone quarried from the mountain sides, but easily accessible mineral deposits may have been easily exhausted or have become valueless for want of fuel through deforestation. Such causes may have determined the fate of nations that lived and perished in the steppes of central Asia,

leaving no record, even mythical, other than scanty ruins, now entombed in the drifting sand-dunes. Historics dwell upon the doings of kings and knights, but usually fail to tell the young student that carpets and table-forks were articles of luxury in the time of Queen Elizabeth of England, that is, about the middle of the 17th century, less than three hundred years ago. Looking back at the social amenities of that period, and comparing them with those we enjoy today, the latter seem to be veritable products of a wizard's wand.

The first vital episode in the history of mining was the discovery that coal was an available fuel. At this date it is such an essential element in the scheme of our existence, that it is difficult to realize that England only began to mine it commercially early in the 13th century, or about 700 years ago, under the name of sea-coal (to distinguish it from wood-charcoal), given to it because it reached London by water, land transportation in those days being impossible. Roads, as we know them, were non-existent.

The mysteries beneath the surface of the earth were not unlocked until Newcomen and Watt gave us the master-key when they produced a practical steam-engine about 1775, not more than 150 years ago. Newcomen depended upon the expansive power of steam for one stroke of the piston and atmospheric pressure for the other. Watt used steam for both strokes, keeping the cylinder hot, and this today is the basis of all engines using steam as motive power. Small as was the change, it has had an influence on civilization beyond conception. From that day the advance has been of ever-increasing rapidity. Each completed engine made it possible to forge and build engines of greater size and power, until we are now able to embody the strength of 50,000 horses in one unit and forge enormous ingots under 1000-ton hammers; and every part of these machines has been retrieved by the mining industry from the subterranean treasure-houses of the world. The stimulation of research into the hidden qualities of the metallic elements went hand in hand with this development and evolved the locomotive, the ocean steamer, the automobile, and the intricate machinery of a thousand industries, to be followed by the aeroplane, the telegraph, telephone, and wireless, and the other marvels that have followed in the wake of the harnessing of electricity to the daily routine of life. To visualize the marvelous transformation we must realize that the mastery of the metals has done more in a century and a half for the physical well-being of the human race than the entire 6000 years which preceded them. Coal

THE PERSEVERANCE (ALASKA GOLD) MINE AND THE ALASKA JUNEAU

and iron have been the moving factors in this process of civilization.

It is only necessary to look over the contents of a modern dwelling to realize the truth of the foregoing statements. There is not one item that is not made out of one or more of the major metals, or on which they have not been employed in their fashioning or transportation to their present place. The stone was wrought with iron tools; the brick was molded by machinery; the lumber was cut with steel saws and worked by chisel and plane; the gas and water were brought in iron pipes, the electricity by iron or copper wires; the curtains, carpets, clothes, and table linen were woven on metallic looms; the furniture, ornaments, and kitchen utensils have all felt the touch of steel; the entire structure of the house and its contents have been assembled from the four quarters of the globe by methods of transportation dependent on iron and coal for their existence.

The productive industries that have furnished the raw material out of which the house has been erected and its contents manufactured are in the order of their relative importance, fishing, lumbering, agriculture, and mining. Fishing was a purely local industry, until boxes and barrels were made; until metal retainers were introduced for the canned product, and cold storage solved the question of the distribution of the fresh article, and a vast transportation system permitted the use of the perishable food at long distance from the point of production.

In like manner lumbering became an industry with the introduction of metal wedges, axes, and saws, gradually expanding with the building of power-driven mills supplied by means of tramways and locomotives with their necessary metallic chains, ropes, and other inci-

dentals; but the industry could never have attained its present importance without the existence of ramified transportation lines reaching every point on the continent and beyond the seas.

Similarly, agriculture could never have fed the teeming multitudes in the large cities had it not been for the introduction of metal plows, steam-plows, reapers, and threshers, vastly increasing the productive power of each human unit beyond the requirements of his own immediate family; but the surplus would have been a waste product had not a system of rail and water transportation made possible the distribution of this extra product to the millions of artisans engaged in converting the raw products of the forests, plains, and mountains into available form; or to the other millions engaged in distributing these finished products to the lumber-men and agriculturists, as well as to the workers in the mines who also are non-producers of food and clothing and only partly of building material.

A people dependent on the lumber interest alone can never become a world power, neither can a purely agricultural community reach the same elevation, even if possessed of rapid transportation. Being compelled to import their mineral supplies, they cannot successfully enter the manufacturing field in competition with other communities amply supplied with the minerals that dominate our existing social fabric.

The mining industry is the one that vitalizes all the others, that makes their expansion possible. It furnishes the fishing, lumber, and agricultural industries with the tools of their trades. It has made it possible to house and clothe and feed the dense centres of population; to conserve surplus perishable food against periods of

MINES. THE EBNER IS ON THE EXTREME RIGHT OF THE SAME RIDGE

small production; to spin the cotton, flax, wool, jute, and other textile materials in quantities absolutely impossible by hand-labor; it furnishes the light, heat, and motive power of the nations; it has brought to the worker luxuries unknown to his forefathers; its beneficent influence is felt by all every minute of the day; and, by increasing the facilities for travel, it is lengthening the available working hours of the human race, through the saving of time. Moreover, it has given the nations a better knowledge of each other, broadening our sympathies, breaking down racial barriers, and hastening the brotherhood of man. Science is dependent upon it for all its instruments of precision; the world is dependent upon it for the education of its swarming millions! The one blot on its escutcheon is that it also furnishes the terrific engines of war, which have kept pace with our peaceful advance by their increased variety and destructiveness. Every shell is one nail more in the nation by which it is fired, a discount on its future resources.

Its culminating effects are seen and felt in the increased size and speed of vessels engaged in the ocean traffic; and in the hundreds of thousands of miles of railway that have covered the world with an intricate network reaching even its remotest corners. It is this system that has built up the congested centres of population with their varied industries, and it is imperative that the system be kept in perfect working order, and expanded steadily to satisfy the demands of the ever-increasing number living under these conditions.

No city ever contains within its boundaries supplies of coal and food-stuffs for more than a brief period, and with its railroad arteries in possession of an enemy must soon succumb to famine or perish with cold. Natural

causes, such as floods, snow, or excessive cold, may produce a blockade almost as effective, as shown by the unfortunate combination of all these adverse factors on the Atlantic coast of the United States last winter when, in spite of an abundance of the required articles, it was a physical impossibility at times to place them within reach of those who needed them so urgently.

The subject might be expanded indefinitely, but the thoughts suggested should suffice to convince the most skeptical, if followed to their ultimate conclusions. In every case it will lead to the truth of the caption at the head of these pages; that the mining industry is the keystone of modern civilization. It follows that a nation with abundant mineral resources can face the world, for all other nations not equally endowed will send it their choicest products in exchange therefor, but when, in addition to metallic wealth, it possesses boundless resources in the shape of forests, fertile plains, and prolific fisheries, it can command the world. Nations have cast covetous eyes upon and have fought for the mineral wealth of their more fortunate neighbors for centuries. Belgium and the Rhenish provinces have been such a battle-ground; hand out your gold was the everlasting cry of the Spanish conquistadores!

In view, therefore, of the absolute necessity of an abundant supply of coal, iron, oil, copper, tin, lead, and zinc, to say nothing of the minor metals, or of gold and silver, for the maintenance of the present physical conditions of life and their expansion in the future, it becomes interesting to sketch the origin of mineral deposits and the amount available for the generations that will follow us; for on these possibilities depends the chance of further industrial development, or of a gradual decay due to

the exhaustion of the raw materials on which it is based.

We can re-forest denuded acres and maintain the fertility of the soil by the conservation of fertilizing matter and periods of rest; we can re-stock depleted waters with fish raised artificially, but it is absolutely certain that human effort can never make an ore deposit. For these we must depend on the operation of natural forces, acting over periods of time inconceivably great. Such forces are the gradual disintegration of the rocky crust of the earth by rainfall, sunshine, frost, and wind; the solution of the liberated particles by underground waters and their transportation to a place of rest, often far-distant from the place of origin, such points being determined by chemical conditions or imperfectly understood forces. In general terms, all metallic orebodies have been formed by such a sequence of events. Petroleum and natural gas are, in part at least, the chemically re-arranged elements of animal and vegetal life that lived, died, and were buried on prehistoric shores millions of years ago; whereas coal, even of inferior quality, has a similar antiquity; and the deeper-seated superior varieties are many times more old.

It is plainly evident that men are mining and using all of these materials more rapidly than nature is collecting or depositing them in available form; and it is equally evident that in any one locality the daily extraction from known sources is depleting the visible supply of that region, and that avoidable waste is a national crime for which future generations will rightly hold us responsible. The time may come when a nation will have to place an embargo on the export of such raw material to ensure its own stability and integrity.

Every mineral deposit has definite boundaries, or, in other words, it is limited in length, breadth, and depth. Within these limits there is a certain amount of material that can be profitably extracted by present methods, and a further quantity that may become available in the future with improved appliances, but there will inevitably come a time when even this will be exhausted. Every mineral deposit now being worked is going through this process, a fact calling for the utmost economy in their exploitation, as well as in the conservation of their finished products, and for a critical examination of the public domain for other bodies to supply the future demand. Fifty years exhausted the bonanzas of the great Comstock lode in Nevada, and left a rabbit-warren four miles long and three thousand feet deep!

Following out this conception to its ultimate conclusion, modern civilization must perish with the exhaustion of the mineral deposits on which it is based. We are not prepared to say that unknown forces may not be discovered to invalidate the conclusion, but, unless they are, the drift of the world today is toward a return to the most primitive conditions of human life. We cannot, however, realize the possibilities of the discovery of such new sources of energy unless they are to be found in latent qualities of the mineral elements as yet unexploited. In the meantime the centres of dense population will shift from country to country, and commercial supremacy from continent to continent, as the flood of

mineral production reaches its maximum or declines in different regions.

It must not be understood from the above that the world is anywhere near such a debacle. The picture has been sketched in harsh lines and deep shadows to emphasize the overwhelming importance of the mining industry. The potential possibilities of Africa, China, South America, and other vast regions within as well as without our own boundaries, besides the steadily increasing population of the world, demands that these be made available and fostered by wise and liberal legislation, instead of being crippled by crude ideas of the meaning of the word 'conservation.' The term implies the existence of a valuable article in which both present and future generations have a vital interest; which may be used by the present possessors, if absolutely unnecessary to their well-being (but used economically and with the least possible waste), leaving the largest possible amount for the use of those to whom the remainder may descend. It is just as absurd to paralyze the industries of a nation for the benefit of posterity, when the present urgently demands the largest possible output, as it would be to tie the hands of the head of a family to save the strength for his children when they are in hourly need of his services.

There is little doubt that mining as a business is looked upon by the conservative mercantile community as a risky proposition best let alone; that in some intangible way it is different from all others, and that success is purely a matter of chance. In fact, it is and must be governed by the factors applied to other lines of effort, and these must be even more rigidly followed because of the one basic radical difference in its stock-in-trade.

In the first place, general business, in which term all industries except mining are included, is carried on under the public eye. Each unit has a stock-in-trade, the value of which is easily ascertainable, the commercial rating and integrity of each individual is known to his banker, and the purchasing public has a good general idea of the sale-value of the articles it desires to purchase. The opportunities for fraudulent operation are comparatively limited, as are also the chances of acquiring a sudden competence. Such an event would certainly be exploited by the newspapers, especially if there might be racy developments, and the general public would certainly know the fact. The merchant can buy from the manufacturer in amounts either large or small. He can begin business on a small scale, expanding from year to year, replenish his stock as required. There is no limit to expansion, if the locality has been wisely selected, except the ability of the manager to handle the establishment, which may be handed down from generation to generation indefinitely.

On the other hand, the miner starts with his capital locked up in the bosom of the earth more securely than in a safety-vault. He cannot replenish it like the fisherman, lumber-man, or farmer. Not until the last pound of ore has been sent to the surface can he tell the amount of his capital. It should be understood that no mineral deposit has anything but a speculative value when first

THE TWIN SHAFTS AND CRUSHING-HOUSE OF THE INSPIRATION CONSOLIDATED COPPER COMPANY

THE ORIGINAL MINE, FORMERLY OWNED BY W. A. CLARK, BUT NOW BELONGING TO THE ANACONDA COPPER MINING COMPANY

discovered, however great its potential value. Positive value can only be acquired by honeycombing the orebody with shafts, drifts, and tunnels so that its dimensions can be measured and the value of the material ascertained by sampling and assay; and not until it is exhausted can the balance-sheet be made up, to ascertain whether the gross yield of the resultant metal has paid all the costs of development, labor, machinery, transportation, reduction, management, taxes, insurance, and other minor expenses, or has left a deficit. Even with a showing of financial failure the enterprise may have been profitable to the nation; for whether the amount be large or small, the metal produced from the mine is an increase in the tangible assets. Executive ability of the highest order is evidently essential.

The fostering of the industry may be accomplished in several ways: by modification of national laws to ensure certainty of title, and State laws to curb the activities of fraudulent operators, and by impressing on the general public the necessity for giving it both moral and financial support. The actual mining laws as passed by the Congress of the United States cover but a few pages, while the interpretation by the courts occupy sufficient volumes to make a library. These decisions are as diverse as the one hundred and fifty creeds founded on the Bible; no better evidence of the necessity of revision is necessary.

The law of 1866 was drafted to cover the particular case of the Comstock in Nevada and granted ownership to a given number of feet on the length of the lode. Its principal result was a crop of litigation in which an army of attorneys was paid to serve or to withhold their services at a cost of millions of dollars, which should have been disbursed as dividends. At that time the knowledge of mining geology in the United States was in its infancy, and was more theoretical than practical. Titles were held largely under the regulations of miners' organizations, and varied according to local ideas of the conditions required to give a locator a valid right to his claim as regarded size and the labor question. An applicant for a patent had to file a copy of these laws or regulations, if such existed, to show that he had complied with them.

The law of 1872 was an attempt to improve that of 1866 by granting the applicant the right to a certain amount of ground, for working purposes, on each side of the centre of the lode, to and not exceeding 300 ft., nor less than 50, and made it compulsory that the end-lines be parallel, so that the length granted on the lode should remain the same at all depths. It also granted the right to follow the vein on its dip beyond the side-lines of the claim should the flatness of the dip so take it. These features might have been satisfactory if all veins followed straight lines and dipped with mathematical precision, but they take no note of the varying character of orebodies, or of the vagaries of nature in the shape of faults, foldings, crossings, etc. The result has again been endless litigation, and no certainty of title even after a patent has been granted.

There is palpable need for a radical revision of laws

causing a diversion of so many millions of dollars (which should have been disbursed as dividends to the mine stockholders) into the pockets of the non-producing legal fraternity. National legislation should be so framed as to make a patent to mining ground as inviolable as that granted to an agricultural homesteader; the individual States should regulate the manner in which the statutory work should be done; also the manner of recording locations and annual labor; and so amend their corporation laws as to curb the activities of the fraudulent operator, and cast some shadow of protection over the minority stockholders. Climate and the different topographical conditions in the different mining States make it difficult to equitably regulate many details in a general law. The question of what these laws should cover and how they should be worded is too great for discussion here. Suffice it to say, that clarity of language is absolutely essential. The mixed use of the words 'locator,' 'assignee,' 'person,' and 'individual' in the Alaska placer law has resulted in at least three different interpretations of its meaning.

Wise legislation surely will do more for the careful exploitation of the mineral resources of the nation than all conservation laws, which have for their basis the assumption that all men connected with the mining industry are dishonest and that all their efforts are saturated with fraud and perjury.

There was little, if any necessity, for laws governing the sale of mineral lands before the discovery of gold in California started the wave of migration westward and disclosed the existence of vast regions rich in valuable mineral deposits of which the people east of the Mississippi had never dreamed. In the eastern States the great bulk of the mineral lands had passed into private ownership, and could be handled without special legislation. The Great West was to the East an unknown quantity, and with all due respect to the force of early education, or the want of it, the ignorance of its social life and material progress is nearly as dense today as it was fifty years ago. Eastern people apparently have no conception of the problems that confront new communities living under conditions different from those with which they are familiar, and they suffer from the delusion of old age, that it knows more than its children as to what is better for them than they do themselves. They find it hard to realize that the children have grown up and may have decided views of their own. By all means let the States regulate their own affairs, in non-national matters, in the way best suited to the conditions nature has imposed upon them.

The fierce legal battles over the millions of dollars involved have been for years before the public through newspaper scare-heads and have doubtless contributed, with other causes, to the widespread impression that mining is a gamble and that success is due to chance pure and simple. It has been shown, however, that every individual in a nation has a vital interest in the continued activity of the industry; not only those whose income and daily bread are the result of mineral development, but every manufacturer who uses machinery of any kind, and every wholesale merchant, middleman, and retailer

engaged in the distribution of the manufactured products, as well as every member of the clerical force and the vast army of laborers dependent on a daily wage. No member of the community is exempt. The fact is tacitly, though in most cases unconsciously, admitted by the general acceptance of the condition of the iron and steel market as indicating the pulse of the nation's commercial prosperity.

The popular conception of the word 'gambling' as applied to mining, is that of a man sitting in a game of cards, dice, or roulette; that everything is due to chance, plus the liability of confronting a variety of crooked schemes skillfully manipulated by the promoters of the game, but that he may win a big stake if he plays long enough. Eliminate this element of chicanery from the word gamble and apply to the mining industry the same common-sense and business rules that are demanded in all other industries and they meet on a common plane. Neither can take the holier-than-thou attitude or call the other black.

The probate of their wills shows how few of the young men who face the world with their college sheepskins have made a monetary success through brains and suavity of manners. The millions of men who annually start on a manufacturing or mercantile career take the chances of being able to steer a winning course through the pitfalls of competition, lack of capital, deficient judgment in selecting a suitable location, shifting of business centre, poor financial training, inability to understand human nature, lack of persistence and quick thought in emergencies, besides other troubles that pop up unexpectedly at each turning of a corner. The small percentage of those that become captains of industry, the records of proceedings and bankruptcy, and the constantly changing occupancy of the smaller stores in the large cities, all testify to the uncertainty of success. If gambling be an attempt to secure something of value when there is a large and unknown number of factors working against the effort, then not only mining but all business is a gamble, and as some cynic has put it, "birth, life, marriage, and even death is a gamble."

Like the merchant, the miner is subject to similar conditions. In the business of each there is and has been varying degrees of sharp practice and more than a suspicion of underhand methods, but unfortunately the exploitation of mineral resources is the only one that has acquired a sinister reputation, and the eradication of this sentiment is as difficult a problem as it is to rehabilitate the character of a dog that has been given a bad name, truthfully or otherwise. The task must, however, be attempted. The industries that now withhold the helping hand must be taught how vitally they are interested. In estimating their profits, allowance is always made for bad debts and bankruptcies, and they should be prepared to assist in the support of State institutions designed to watch over and protect the interests of investors in mining enterprises during their infancy. Such watchful care is extended by Chambers of Commerce and similar organizations to other industries at the expense of the raw materials on which such industries depend

for existence. There are large communities whose life depends upon the abundance of mineral production, where a man trying to finance a mine is looked upon as crazy, because, to use a Californian euphemism, he is in a 'cow-country' or an agricultural region; or a strategic point as a port-of-entry for foreign commerce.

Our merchants everywhere must be educated to the fact that mining is as honorable a business as any other, that it takes money to finance any business, whatever its character; that spectacular success of any kind is rare and is the result of good judgment and persistent effort; that it takes years to open a big mine as it took years to build up the big mail-houses or the Baldwin locomotive works, and that in self-defence they are bound to foster, in every conceivable way, the basic industry that is the foundation of all business and of the complex fabric of modern civilization.

Coal, oil, and the metals, are the materials of which this foundation is constructed. To limit their production at this date on the plea that they may be wanted in the future by posterity is folly beyond expression in words. We are fighting that we may have a balance to deliver. To limit production may cause us to fail in realizing the day when less of these absolutely invaluable things will be diverted to the engines of war, and more be made available for the occupation of peace.

Occurrence of Metals in Nature

The following descriptions, while apparently elementary, are refreshing to all in the mining industry:

- Aluminum as the silicate.
- Antimony as the sulphide.
- Arsenic as the sulphide.
- Barium as the sulphate.
- Bismuth as the oxide, sulphide; also metallic.
- Cadmium as the oxide, carbonate, and sulphide.
- Calcium as the carbonate, sulphate, and silicate.
- Chromium as the oxide.
- Cobalt as the sulphide.
- Copper as the sulphide, oxide, and carbonate.
- Gold as the metal or telluride.
- Iron as the oxide, sulphide, and carbonate.
- Lead as the sulphide.
- Magnesium as the carbonate, sulphate, and silicate.
- Manganese as the oxide.
- Mercury as the metal or sulphide.
- Nickel as the sulphide.
- Silver as the metal or sulphide.
- Sodium as the chloride and silicate.
- Strontium as the carbonate, sulphate, and silicate.
- Tin as the oxide.
- Zinc as the oxide, carbonate, and sulphide.—E. R. Doering in 'Chemical Engineer.'

PYRITE is now being produced as a by-product from coal mining, the pyritiferous slates, formerly thrown into the gob, being concentrated. This will add materially to the revenue at many mines that have large amounts of slate-band rich in pyrite.

By-Passing Ore From Stamp-Feeders to Tube-Mills

*Stamp-mill capacity is considerably increased by screening out the fine ore and sending it direct to tube-mills, that is, the material from the crushers finer than the screen used on the mortar-boxes. According to E. H. Johnson the device consists of a bell-mouthed trommel 21 in. long, 26 in. diameter at the narrow end, and 30½ in. at the wide end. It operates as a revolving-perforated

SECTION OF STAMP-MILL SHOWING FEEDER AND TROMMEL FOR BY-PASSING FINE ORE. THE MORTAR STANDS ON A CAST ANVIL, A FEATURE OF RAND PRACTICE.

chute between the Challenge feeder and the mortar-box. The screen on the trommel is a perforated plate with holes $\frac{3}{8}$ by $1\frac{1}{4}$ in. The material passing the screen falls into a launder passing outside the battery king-post into a launder leading to the tube-mill cones. The effect on crushing is not only to eliminate from the mortar-box the material fine enough for tube-milling, but also avoids the cushioning effect to the stamps this material causes. The trommels are driven through an intermediary shaft from the line-shaft, and revolve at 16 r.p.m. The maintenance cost is low, the perforated screen ($\frac{1}{4}$ -in. plate)

*Abstract from 'Journal' of C., M. & M. Society of South Africa.

lasting nine months, while the only other parts requiring renewal are the small supporting rollers. The rate of feed is, of course, governed entirely by the battery-feeder.

Some time ago an opportunity presented itself to show what this by-passing amounted to, a section of the plant not equipped with the trommels being 'hung-up' for two weeks, enabling a determination of the effect of the trommels to be made. Following are the data obtained:

Stamps dropping	110
Weight of stamps, pounds	1450
Running time, days	11.2417
Ore crushed, tons	28.322
Duty per stamp, tons	22.9
Tube-mills working	11
Running time, days	12.1256
Screen-aperture, inches	0.32
Duty per nominal crushing-unit, tons*	19.74
Minus 90-mesh duty per tube-mill per day, tons	147.5
Minus 90-mesh duty per nominal per day crushing-unit, tons	4.588
Slime, per cent.	56.1
Minus 90-mesh in pulp	88.1
Minus 200-mesh in pulp	74.0

*The nominal crushing-unit, familiar to Rand millmen, is used to render comparison easy. For those unacquainted with this empirical formula a unit is a 1250-lb. stamp, and a 22 by 5½-ft. tube-mill is equivalent to 30 units.

Gradings:

	%	%	%	%
	+60	+90	-90	-200
Screen grading	75.9	5.5	18.6	...
Sand residue	1.7	25.3	31.4	41.6
Slime residue	0.7	99.3

PURE MOLYBDENUM is a white metal, softer than steel, malleable, and capable of being forged and welded. It can be filed and polished, and may be drawn into ribbons and fine wire. It will not scratch glass. Its atomic weight is 96. Its specific gravity varies from 9 to 10, depending upon its physical condition and the manner of its production. Its melting point is about 4500° F., being higher than for copper, iron, or platinum, and lower than for osmium, tantalum, or tungsten. The purest molybdenum is produced from wulfenite, but practically the whole of the world's supply of the metal and its compounds is obtained from molybdenite. Metallic molybdenum is only slowly oxidized at ordinary temperatures and retains its lustre indefinitely, but it oxidizes rapidly at about 1100° F. It is attacked by fluorine at ordinary temperatures, by chlorine at a dull red heat, and by bromine at a cherry red heat. Molybdenum is attacked by nitric acid, and by hot concentrated sulphuric acid, but not by hydrochloric acid.

ANTIMONY is used in enamels, glass-making, vulcanizing, and in paintings; it also constitutes 12½% of the composition of shrapnel bullets, and is employed in smoke-bombs, and in the primers of shells and cartridges. The production of antimony in the United States last year was only 10% of the total consumption. The imports amounted to 10,370 tons of ore and 17,825 tons of the metal, of which 87% came from China, and 12% from Mexico. The expansion of the domestic output is an urgent necessity.

Potash Production of the United States

The output of all potash materials produced and marketed in this country in 1917, as reported by manufacturers to the U. S. Geological Survey, was 126,577 short tons, which contained 32,366 tons, or an average of 26.4% of pure potash (K_2O). This is more than three times the quantity produced in 1916, and corresponds closely with the output predicted for 1917 by H. S. Gale, of the Survey, from a review of the mid-year statistics. The approximate average selling price of these potash materials at the points of shipment was \$4.26 per unit—that is, \$4.26 per ton for every 1% of pure potash (K_2O) in the material marketed. This price corresponds to \$426 per ton of pure potash. The total value of the potash produced in the United States in 1917 was \$13,791,922.

In the following preliminary summary by Mr. Gale, the 1917 production is classified with as much detail as is consistent with the Survey's obligation to hold individual reports of production confidential.

Sources	Pro- ducers	Pro- duction Short tons	Available potash (K_2O) Short tons	Value at point of shipment
Mineral sources:				
Natural brines	10	79,876	20,652	\$8,219,912
Alunite (refined salts and crude and roasted alunite)	3	7,153	2,402	892,763
Dust from cement mills	8	13,582	1,621	700,523
Dust from blast-furnaces	3	2,133	185	68,841
Organic sources:				
Kelp	10	11,306	3,572	2,114,815
Molasses residue from distilleries	4	8,589	2,846	1,130,907
Wood ashes	36	700	424	406,856
Evaporated Steffens water from sugar refineries	5	2,593	359	143,430
Evaporated wool washings and miscellaneous industrial wastes	3	645	305	113,875
	82	126,577	32,366	\$13,791,922

*Includes 1333 tons of material produced but not sold in 1917.

The output of one of the four plants producing potash from brines in western Nebraska considerably exceeded that from any other source or district, and the combined output of these plants represents 45% of the total for the entire country. Searles Lake, California, was the other source of large production from brines.

The potash produced from kelp represents 10% of the total. A large part of this was high-grade potassium chloride produced by two companies, while the remainder was divided among eight other producers, who manufactured kelp char or ash carrying 16 to 36% of potash, used as an ingredient of fertilizer. An unexpected shortage of the kelp crop curtailed production from this source in 1917.

Production from alunite was not so great as had been expected, though two additional producers from this source entered the field. The plant of the original producer (Mineral Products Co. at Marysville, Utah) was destroyed by fire in October, and, though the work of reconstructing it has been pushed rapidly, it had not been put into operation by the end of the year. (It is now working, May 1918.) In addition to the high-grade potassium sulphate produced from alunite a consider-

able quantity of calcined alunite carrying 16% of available potash was marketed for incorporation into fertilizers, and raw alunite was shipped to Eastern reduction works to be treated for the recovery of potash.

A fairly high-grade potash produced from the residue of charred molasses at alcohol distilleries, representing nearly 9% of the total output, was, like kelp char, used in fertilizer mixtures.

The quantity of potash recovered from the waste liquors produced by the Steffens process of beet-sugar manufacture was somewhat augmented in 1917. Many experiments designed to increase the output from this source are being made at beet-sugar factories throughout the country.

Eight cement mills reported production of potash salts or of potash-rich dust sold as fertilizer during the year, the quantity marketed from this source reaching a total of 13,582 short tons, representing 1621 tons of actual potash (K_2O). The recovery of potash from cement dust, which is being rapidly extended, seems to offer large promise for a greater domestic potash industry, and it is expected that the production from this source may take second place in the summary by sources for 1918. (This material is collected by means of the Cottrell electric precipitator.)

Dust collected from blast-furnaces is a significant though still a minor item in the total for 1917. Production from this source may eventually be large.

Crude potash is still produced by the old methods of leaching from wood-ash in the hardwood lumber districts, chiefly in Wisconsin and Michigan. Complete statistics of this output are difficult to obtain. Reports from 36 producers in 1917 show a gross output marketed of 700 short tons, having a value of \$406,856. This is assumed to be about 424 short tons of K_2O .

Refined potash salts were produced from wool washings in 1917 by at least two plants, and some potash was produced from the ash or char obtained by burning other waste organic matter at several industrial establishments.

Potash was produced in 1917 by 82 firms, including 36 wood-ash leachers, most of them operating small works. The total production is about 13% of the normal consumption of potash in the country during the years immediately preceding the War. There is now no crisis as regards the potash supply of the country, though the prices paid for what is obtained are about ten times the normal prices before the War. All firms have been seriously handicapped by shortage of labor and fuel, difficulties of transportation and inability to get needed equipment. Potash-producing plants have been generally included among the industries that are necessary to win the War, and there is a widespread sentiment in favor of assisting, so far as possible, the operations of these plants by giving special consideration to their actual needs. It is exceedingly unlikely, however, that Government operation or any direct Government financial aid to new enterprises for producing potash will now be considered necessary, in view of the successful results obtained from the many privately-conducted projects.

Sulphur, Pyrite, and Sulphuric Acid in 1917

SULPHUR. Sulphur was produced in 1917 by eight mines, one in Louisiana, two each in Texas, Nevada, and Wyoming, and one in Colorado. According to the U. S. Geological Survey the production in 1917 was 50% greater than in 1916, and the indications point to a still further increase in 1918.

Statistics received from the Bureau of Foreign and Domestic Commerce show that 973 long tons of sulphur was imported into the United States in 1917 and that 152,831 tons was exported. Imports in 1917 were less than 5% of those in 1916, but exports were more than 18% greater than in 1916, and were the largest ever made from this country in a single year. The total value of the sulphur exported in 1917 was \$3,504,661, which would indicate an average value of \$22.93 per ton.

PYRITE. The pyrite industry showed an unsettled condition in 1917, due largely to uncertainty as to whether importation of foreign pyrite would be continued. In spite of this uncertainty, however, the domestic production was about 10% greater than in 1916. Statistics collected by the Survey show a total production of 462,662 tons, valued at \$2,485,435. The two States making the largest output were Virginia and California, which together produced nearly 300,000 long tons.

The quantity of pyritic ore imported last year was notably less than that imported during the years preceding the War. The total imports of pyrite in 1917 was 967,340 tons, valued at \$5,980,457. Of this, 214,115 tons came from Canada and Newfoundland, and 753,225 tons from Spain and Portugal. The principal cause of the decline in the imports was the difficulty of obtaining ships to bring ore from Spain. An increase in the imports of pyrite from Canada is expected in 1918, but on the other hand, a still greater decrease in imports from Spain is probable.

SULPHURIC ACID. The quantity of sulphuric acid produced in 1917 was nearly twice as great as that produced in 1913, which may be taken as a normal before-the-War year.

The output of sulphuric acid last year, expressed in terms of acid of 50°B., was 5,967,551 short tons, valued at \$71,505,536, to which must be added 759,039 tons of acids of strengths higher than 66°B. (which cannot be calculated for comparison with acid of 50°B.) valued at \$16,034,545. The increase over 1916 in the production of acid expressed as 50°B. was therefore more than 325,000 tons and \$8,800,000 in value, and the increase in the production of stronger acids was more than 315,000 tons and \$5,225,000 in value. The value of the total production of the acid in 1917 was over \$14,000,000 more than in 1916.

The foregoing totals include by-product acid—that is, produced at copper and zinc smelters. The yield from this source in 1917, expressed as acid of 60°B., was 1,336,209 tons, valued at \$14,516,104, to which must be added 119,048 tons of strengths higher than 66°B. (which

cannot be calculated as acid of 60°B.), valued at \$2,374,341.

Statistics collected by the Survey show that 221 plants in 33 States produced acid in 1917. Of these, 139 made acid of 50°B., 66 acid of 60°B., 60 acid of 66°B., and 38 acid of higher strengths. Pennsylvania and New Jersey made acid valued at more than \$10,000,000 each, and Virginia, Maryland, Illinois, and Georgia each acid valued at more than \$5,000,000. The value of the total production of these six States amounted to over \$50,000,000, or considerably more than half of the entire value of the acid produced in the country.

The following quantities and kinds of sulphur ore were used in making sulphuric acid in 1917, in tons:

	Domestic	Foreign	Total
Sulphur	463,364	20,463	483,827
Pyrite	376,955	889,183	1,257,138
Gold and silver-bearing pyrite and galena	17,980	17,980
Copper-bearing sulphides	708,502	147,531	856,033
Zinc-bearing sulphides	584,100	152,811	736,911

Statistics received from the Bureau of Foreign and Domestic Commerce show that 4287 tons of sulphuric acid, valued at \$98,232, was imported into the United States in 1917, and that 31,771 tons, valued at \$1,600,125, was exported.

Standardization of Deci-normal Sulphuric Acid

The best procedure, according to F. W. Babington and A. Tingle (Jour. Soc. Chem. Ind.), is to select a suitable acid and compare its solutions volumetrically with the acid to be standardized. Either tartaric acid or salicylic acid is suitable for this purpose. Both are cheap, readily obtained in a state of purity, both have high molecular weights, are anhydrous, and keep well when dry. Salicylic acid can be used only in alcoholic solution, and tartaric acid is subject to change if the solutions are kept too long. To 25 cc. portions of a standard solution of H_2SO_4 , the following methods were applied: (1) titration in comparison with tartaric acid; (2) titration in comparison with salicylic acid; (3) direct precipitation with $BaCl_2$; (4) direct precipitation with excess $Ba(OH)_2$; (5) exact neutralization with $Ba(OH)_2$, using phenolphthalein; (6) evaporation of $Ba(OH)_2$ with excess of acid and calculation from the titration; (7) addition of excess H_2SO_4 to $Ba(OH)_2$ and filtration with calculation from titration. The corresponding amounts of $BaSO_4$ obtained were, in grammes, 0.2924, 0.2924, 0.2949, 0.2915, 0.2735, 0.2868, and 0.2837, respectively. In the standardization of solutions, 0.1 normal or weaker, any method involving the weighing of $BaSO_4$ is liable to a larger experimental error than is titration, since 0.1 cc. 0.1 N acid is equivalent to 1.17 mg. $BaSO_4$. The results from (1) and (2) are probably correct, judging from the concordance with each other and with those from (4); the result from (3) is low because of the occlusion of $BaCl_2$; incomplete precipitation is the cause of loss in (5); the presence of an alkali silicate would best account for the discrepancy among (4), (6), and (7).

REVIEW OF MINING

BINGHAM, UTAH

Fire Problems at Utah Apex Mine.—Montana-Bingham and Utah Metal Reports.

Engineering problems encountered during the fire at the Utah Apex mine late in March 1917 were recently described by V. S. Rood and J. A. Norden—manager and assistant

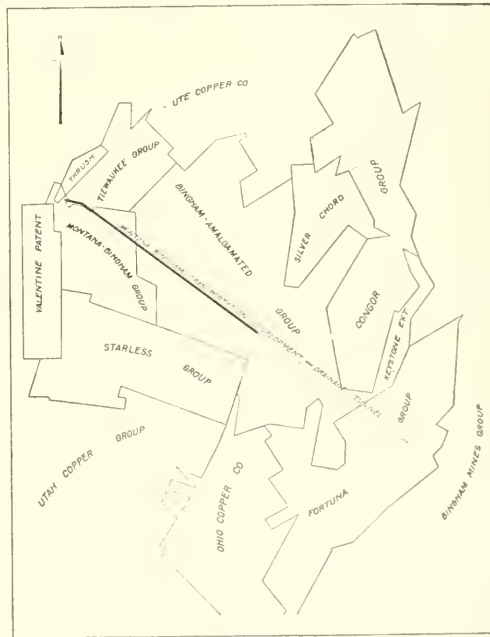

PART OF UTAH APEX MINE, SHOWING FIRE-ZONE

superintendent for the company—to the Utah Society of Engineers at Salt Lake City. From a 3-compartment shaft, levels had been driven to the orebodies. The 1000-ft. level, about 4000 ft. long, was a haulage and drainage-adit. Other workings are down to 1500 ft. Ore carries lead, gold, and silver. The orebody is mostly in a crushed and faulted limestone, also sometimes in lenses of black pyritic shale. In mining above 1000 ft. regular square-set and filling methods were used, but with indifferent success. The filling—limestone, shale, and pyrite—swelled, oxidized, and produced considerable heat. Extraction above 1150-ft. level was afterward done successfully by top-slicing. The caved material and mat of timber produced some heat, but of no consequence. On 1300-ft. level, square-sets were tried again. Although ventilating raises were put up, the filling became as hot as 98° F., even where there was plenty of air. Top-slicing was also used here on several ore-shoots, but slices frequently broke through the thin walls of the stopes, exposing the heating filling of the old stope. Early in 1917 the 1500-ft. level cut the orebody, and in March it was being prepared for stoping by sluicing, when No. 11 raise emitted odors that showed the mine to be on fire. After considering the problem, it was decided to flood the mine to the 1100-ft. level. About 15,000,000 gal. of water was forced into the workings from March 27 to April 10. Unwatering was done by balling from April 20 to May 27. After cleaning up the levels, concrete bulkheads were placed at all openings leading to the fire-zone. The total cost of combating the fire was \$42,884.

The Utah Metal & Tunnel Co. has issued its report for 1917, showing the following comparison of results:

	1917	1916	1915
Gold, ounces.....	4,612	17,934	16,914
Silver, ounces.....	242,003	388,757	475,894
Copper, pounds.....	659,127	1,761,520	2,873,815
Lead, pounds.....	5,348,610	6,301,670	9,860,089
Gross value.....	\$ 884,688	\$1,499,268	\$1,386,845
Net profit.....	40,993	528,737
Balance at end of year.....	1,057,492	1,511,949
Dividends paid.....	553,262	342,473
Current assets.....	233,434	774,117
Current liabilities.....	51,093	66,662

Operations were handicapped in many ways during the past year. The great need of this property is development. Adjacent properties have given good results, so should the Utah Metal mines. At least six lime-bed formations exist, in which mineral deposits are expected to be found. A large

PART OF BINGHAM DISTRICT, UTAH

quantity of high-grade lead ore has been opened in one, but the claim is in dispute. In the Utah Metal and Bingham-New Haven ground large tonnages of low-grade lead ore has been developed. The mill has now 300 tons capacity.

Montana-Bingham Consolidated Mining Co. has issued a report showing its condition at April 1, 1918. Property consists of the Fortuna claims of 171 acres, Eddie of 50 acres,

Tiewaukee of 45 acres, and Thrush and Valentine of 46 acres. Company owns 20% of issued shares of Bingham Amalgamated Mining Co. In the Fortuna claims three tunnels have been driven, but the best development is in the Mayflower where 1000 ft. of ore averages 2% copper. A 150-ton flotation mill and full mining equipment is in use here. On the Bingham side of the property, at the Thrush, a 7 by 7-ft. transportation tunnel has been driven 5900 ft. This is 600 ft. below Keystone tunnel of the Fortuna. The Bingham Coalition Mines Co.'s 150-ton mill is to be leased and improved. With the two mills a profit of \$18,000 monthly is calculated upon. Other developments are entirely satisfactory. Excess of liabilities is \$506,024, but directors do not consider this serious. On May 8 an assessment of 10c. per share was to be levied. This will yield \$230,000.

ELY, NEVADA

Liberty Loan Subscriptions.—Consolidated Coppermines Finds Rich Ore.—Coal-Dust Firing at McGill.

It is claimed that Nevada stands at the top of all the States for total over-subscription to the third Liberty Loan, also by the greatest number of individual subscribers—24,000—out of a population of 111,000. In one of the store windows at Ely there is on display the Honor Flag, with four stars, given to White Pine county by the Government for over-subscribing the loan four times.

Consolidated Coppermines is operating both units of its mill. In drilling for air recently, near the old caved Alpha shaft, a large body of copper carbonate ore was discovered. This is at 400 ft. depth; heretofore none has been found above the 700-ft. level. Considerable high-grade ore is being taken out from the 11th and 12th levels, a continuation of the rich shoots on No. 7 and 10, which was mined last year.

The Ward mine is shipping 45 tons daily of a lead-silver ore.

Little manganese ore is being shipped lately, as the pockets have been exhausted.

There is about 600 tons of lead-silver ore at Hamilton, which is being hauled to Kimberley for shipment to smelter.

Nevada Consolidated's fine new coal-crushing plant erected last year, was recently put in operation. Previously sufficient coal could not be obtained, and the company had to continue using fuel-oil at high cost. The new system saves over \$1 per ton of ore milled.

VICTORIA, BRITISH COLUMBIA

Coal Production and Use of Powdered Coal.

Coal production of British Columbia in April totaled 224,992 tons. Vancouver Island collieries yielded 148,078 tons, Crow's Nest Pass 62,641 tons, and Nicola-Princeton 14,253 tons. The total for 4 months is 77,272 tons ahead of the same period of 1917. Two new mines will be producing 500 tons daily each by the end of the year, namely, those of the Granby Consolidated and Canadian Collieries.

The use of powdered coal to replace fuel-oil is being tried in this Province at present. At Vancouver the B. C. Sugar Refining Co., one of the largest of the Province's industries, has erected a plant to provide for the change and, it is understood, is getting satisfactory results. The Canadian Collieries (Dunsmuir) Ltd., anticipating a demand for the new fuel, is making tests of waste from its washery that has been accumulating for years in the harbor at Ladysmith. If results are satisfactory the company will put in pulverizing equipment and will proceed with the reclamation of this refuse, of which there must be four or five million tons, some of which has been lying under water for 17 years. It is considered probable that, should the experiments turn out well, and providing the United States withdraws the 'oil-tankers' at present in service between Cal-

fornia and British Columbia, the Canadian Pacific Railway will arrange for the use of coal-dust in locomotives now burning oil.

An interesting sidelight on the increased value of coal in the Canadian North-West is obtained from an experience of the Pacific Coast Coal Mines Co. In pre-war days the company discharged its waste into a lagoon, across which a rough cofferdam had been constructed. George Wilkinson, then manager, and now Inspector of Mines for British Columbia, was responsible for this. His idea was that this coal, for which there then was no market, might prove useful in an emergency. Last year 50,000 tons of it was recovered and placed on the market at \$3 per ton.

A new company, known as the Canadian Western Fuel Co., has been incorporated here for the purpose of taking over and operating all the assets in British Columbia of the old Western Fuel Co. of San Francisco. The incorporators are G. W. Owen, J. B. Owen, and John Hunt, and the capital is \$5,000,000. There will be no change in the management as at present constituted, and its headquarters will be at Nanaimo. G. W. Bowen is general manager and John Hunt remains as general superintendent. J. B. Bowen is manager for the Western Mercantile Co., the trading establishment opened by the Western Fuel Co.

The Fuel Controller for Manitoba, T. R. Deaville, is quoted as accusing the coal-mine operators of British Columbia, Alberta, and Saskatchewan as being strangely lacking in business sense and a spirit of co-operation in not starting a campaign with a view to explaining to the people of the Province of Manitoba the quality of the coal of the Western provinces and giving directions as to the best methods of handling and burning it.

An advance in the selling price of coal in British Columbia is expected. That an application to the Fuel Controller for sanction for such a course was expected following the latest increase of 50c. per day granted the coal miners. It is predicted that the increase will be between 50 and 65c. per ton.

Dorreen.—At least \$150,000 will be spent on development of the Fiddler claims situated near here in the Skeena mining division. A considerable proportion of this will be expended this year. It is understood that the Oppenheimer interests of Butte, Montana, are advancing the money, and it is confidently expected that the property will be placed soon on the shipping list. It is situated in the neighborhood of the Rocher de Boule. The ore carries chiefly gold, about \$30 per ton.

LEADVILLE, COLORADO

Labor Situation.—Gold and Manganese.

Labor is rapidly becoming a serious problem here. Following the strike of last year, hundreds of miners left the district for the copper centres of Utah, Arizona, and Montana. Since then more than 300 young men, mostly employed at the mines, have entered military service, and another quota of 100 has been called to leave between May 26 and June 1. The June quotas have not been announced, but it is believed that another large number will be called out during that month. In a town of 10,000 people, where mining offers the main field of employment, requiring the services of approximately 2000 men, these inroads in the available labor supply cause serious results, from a purely mining point of view, and unless offset by some other source than is now known, they will cause a material reduction in production. The Leadville Chamber of Commerce is to take the matter under consideration for the purpose of assisting local operators to secure labor.

The Miller gold mine in Lackawanna gulch is being reopened for the season, in charge of G. W. Buehler.

On Poverty Flats the Jason, Albright No. 2, and Fairview are producing a considerable quantity of manganese ore, 100 tons daily.

THE MINING SUMMARY

ALASKA

Kennecott.—The Kennecott Copper Corporation is to hold 51% of the capital of the Mother Lode Coalition Mines, the new company formed to take over the Mother Lode Copper Co. The 2,500,000 shares will have no par value.

The 1917 report of Kennecott Copper Corporation has been issued, containing the following:

Copper and silver sold realized \$16,026,105. The cost of production was \$4,208,909. Dividends from Utah Copper and other income made a total of \$19,283,481 available, less \$1,318,579 for taxes and interest, leaving \$17,964,902 profit. Dividends absorbed \$10,311,665. The balance on December 31, 1916, was \$18,915,228, and a year later \$8,596,444. Depletion charges for 1916 and 1917 totaled \$17,618,574. Current assets total \$11,280,796, and liabilities \$1,508,419. Investments are valued at \$102,568,396.

New development amounted to 10,770 ft. at Kennecott and 5320 ft. at Latouche; also 14,419 ft. of drilling. Labor was short, and a strike was declared for 47 days at the Bonanza and Jumbo mines, the men demanding more wages. A new double-compartment shaft was completed to 600 ft. at the Bonanza, also additions to the power-plant. Storage-battery locomotives and self-dumping ore-cars were installed underground at Latouche, and the mill and power-plant improved. Operations resulted as under:

	Kennecott mines	Latouche mine
Ore shipped to smelter, tons.....	89,799	49,141
Copper content, per cent.....	38.57	11.48
Ore concentrated, tons.....	206,253	253,805
Copper content, per cent.....	8.92	2.06
Concentrate, tons.....	29,559	29,423
Copper content, per cent.....	53.52	14.20
Recovery, per cent.....	85.98	80.28
Tailing leached by ammonia, tons..	98,075
Copper content, per cent.....	0.90
Total recovery, per cent.....	89.40
Copper produced, pounds.....	78,211,429
Silver produced, ounces.....	933,573
Cost of copper sold and delivered, cents per pound.....	5.38

The company has declared a quarterly dividend of \$1 per share.

A discussion of the geology of the Kennecott region appears on page 785 of this issue.

Nome.—Telegraphic advice on May 30 stated that the ice on Bering sea was breaking up, and navigation to Nome could start at an early date.

ARIZONA

Copper production of this State in 1917 aggregated 76,228,000 lb. This is from 15 large mines and a number of small ones.

Patagonia.—The World's Fair mine in the Harshaw district has been sold to Eastern people. A. A. Holland is now sampling it for the purchasers. About 15,000 ft. of development has been done. Production is said to be \$1,000,-

000, from copper, lead, gold, and silver ores. Reserves are considered to be at least half of this amount.

Wenden.—Rich copper has been opened in the east drift from the shaft of the Little Giant. It is 18 in. of copper glance.

Several Globe men have taken a lease on the Wenden Copper Co.'s property. Three carloads of ore has been shipped.

Yuma.—Additions are being made to the Red Cloud mill, which is working at full capacity. The company is said to be employing 300 men.

CALIFORNIA

Downieville.—Mining in the northern part of Sierra county is said to be much more active than last year. Miners receive \$3 per day plus board, or \$4 without board.

French Gulch.—The Black Toms Mining Co. has driven an adit 1900 ft. on the Niagara ground, and has struck a heavy flow of water. The adit is 450 ft. below the lowest workings of the well-known Niagara mine. Earl J. Barnes is superintendent.

Lewiston.—The Babblew Mining Co. is driving an adit to prospect the river channel on the Paulsen ranch. Hydraulicking has been stopped on account of shortage of water.

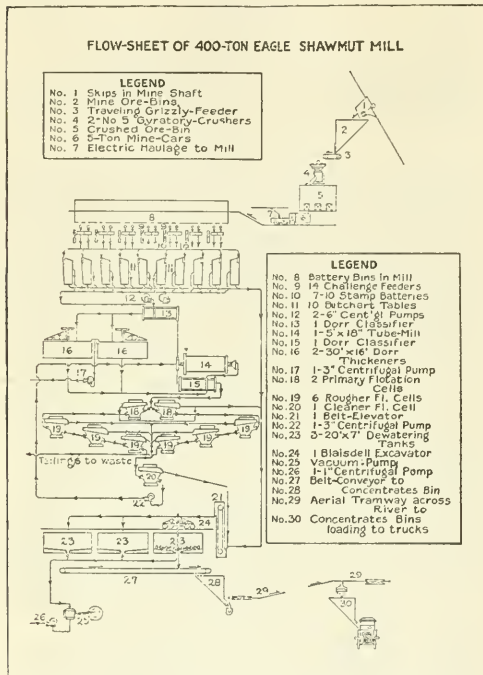

Peanut.—A carload of chrome was shipped from here by way of Redding to Chicago. It is said to be the richest chrome ever mined in this part of the State, the ore carrying 55% Cr₂O₃.

Portola.—Main shaft of the Walker copper mine is down 425 ft., in ore all the way from the 300-ft. level of the main tunnel, which is in 1000 ft. This ore carries 5% copper and \$3 in gold and silver. The mill is concentrating (flotation and tables) 90 tons daily, saving 97%. Concentrate contains 21% copper, and 1400 tons await shipment. V. P. Hart is manager.

Shawmut.—Included in the Tonopah Belmont Development Co. of Nevada report for 1917 is a statement of operations of the Belmont Shawmut Mining Co., which took over the Eagle Shawmut mine in Tuolumne county. E. F. Williamson is superintendent.

During the past year the main three-compartment shaft was sunk and heavily timbered from the 16th level to a further depth of 409 ft.—from 1834 to 2243 ft.—measured from the adit-level; and the new 17th and 18th levels were turned off the shaft at 150 ft. and 350 ft., respectively, below the 16th level. Stations and ore-pockets were cut on No. 16, 17, and 18 levels, and the two latter were driven. On the adit-level a large room was excavated and timbered, and a large electric hoist installed. An underground headframe was built in a suitable excavation, and new skips, cables, and an electric-bell signaling system were installed in the shaft. An adequate electrically driven pump was put in on No. 16 level, and a smaller pump on No. 18, these being connected to pumps on the levels above by proper water-columns. Power-transmission cables connecting up the hoist and pumps were installed. A large amount of work was done on general repairs underground. Old stopes

were put in shape for production, levels that had been crushed were opened and timbered, ventilation connections made, etc. Development has not been, and cannot be, of a character to definitely block out reserve ore. The drift levels cannot be driven on the ore but must, because of heavy and caving vein material, be carried in, or partly in, the firm hanging wall, and the full extent of the ore can only be determined by cross-cuts from drift to foot-wall. The lenticular character of the sulphide ore would necessitate too many of these cross-cuts to fully expose the ore. The main sulphide ore-shoot has been, therefore, but partly developed by the work on No. 17 and 18 levels. From that completed, however, it is believed that the main sulphide ore-shoot, on the horizon of No. 18 level—350 ft. on the dip below No. 16—contains not less, in tonnage and grade, than the average of this shoot on the upper horizons. The

work on the lower levels has, moreover, shown considerable quantities of schist ore, and the new work, as a whole, has met expectations, and has doubtless increased the indicated ore-reserves to double those of March 1, 1917, or to about 318,000 tons. After a great deal of laboratory work on the ore, a process of combined gravity and oil-flotation concentration was devised. For comparison, an actual mill-test of the formerly used amalgamation and gravity concentration process was carefully made, and from the results obtained gravity concentration followed by oil flotation was decided upon, and the re-modeling of the old 100-stamp plate and vanner mill was undertaken. The design follows the flow-sheet shown. The difficulties in re-modeling of an old mill have in this case been largely overcome and the completed plant will be, while not so well arranged as a new plant, perhaps, a convenient and satisfactory mill. Seventy of the original 100 stamps will be used, and the daily capacity is expected to be 400 tons.

Gold production was expected to be started in May 1918.

COLORADO

Gladstone.—The season of 1918 will be marked by extensive development in this district, judging by present indications. A number of old claims are to be re-opened, and various mining interests are paying attention to the district, which has produced rich ore. One of the main handicaps to development is climate; at present snow covers the larger portion. The Ariadne will be among the old mines to be operated.

Silverton.—During April and the first part of May ore shipments were comparatively light due to low temperatures and a heavy cover of snow. The past winter has been exceptional, in that there has been no long period of total inactivity, as in previous years. The high prices of metals, and particularly the favorable climatic conditions, have been conducive to extensive development, almost to steady shipping. During April, 60 cars of ore were shipped.

The Anvil Leasing Co., operating the Emerald vein, is making steady shipments of good copper ore, having billed out seven cars so far.

The Silver Lake Mines (S. D. & G. Leasing Co.) has resumed normal operations, and is sending large quantities of ore to the North Star mill for concentration. Some shipments of crude ore have also been made.

The Mayflower Leasing Co. is shipping large quantities and will soon be producing the normal heavy tonnage of the summer season.

The Dora Consolidated M. & M. Co. shipped a car of ore, after a short period of development.

IDAHO

Adair.—The Big Elk Mining Co. has given control of its property to S. B. Holbert of Pittsburgh, Pennsylvania. He will spend \$25,000 in development, in return receiving a share consideration. A lower adit is to be driven.

Kellogg.—The Douglas zinc mine on Pine creek, operated under lease by the Anaconda company of Butte, has been returned to its owners. It is considered that transportation difficulties were the cause of this action, the wagon-road being almost impossible, and the O.-W. R. & N. Co. is not proceeding with construction of the line down Pine creek. Anaconda has shipped a total of 198 carloads of ore, assaying 25% zinc, 8% lead, and 5 oz. silver. Over 100,000 tons is said to be available. The Anaconda company left the mine in good order. A. McCullum is now in charge.

MICHIGAN

Houghton.—Calumet & Hecla pays \$15 per share on June 14. This makes \$25 for the current year.

Effective June 1, Copper Range Co. increased miners' pay to \$4.25 per shift, pickers \$4, and trammers \$3.85. All bonuses are to be discontinued.

Allouez pays a dividend of \$1.50 per share on June 26. This makes \$4.50 for the year.

MISSOURI

Joplin.—The ore market was much stronger last week. The output of the region was 4860 tons blende, 110 tons calamine, and 1134 tons lead, averaging \$54, \$35, and \$85 per ton, respectively. The total value was \$362,304, making \$9,937,885 for 21 weeks. Missouri contributed \$117,914 to last week's total.

MONTANA

Butte.—Davis-Daly Copper Co. made a profit of \$266,548 during the first quarter of 1918, against \$144,474 in the last quarter of 1917. The output was 19,778 tons of ore, yielding 2,688,150 lb. copper, 205,650 lb. lead, 438,253 lb. zinc, 159,497 oz. silver, and 133 oz. gold. In the previous period 11,891 tons was mined. The Colorado mine will soon be producing 300 tons daily.

The Butte Copper & Zinc Co. made a gross profit of \$226,717 for the first quarter of 1918. Half of this goes to the Anaconda company. Manganese shipments totaled 8300 tons. At present the daily output of this ore is 200 tons, also 100 tons of zinc ore.

Dillon.—The Crystal Graphite Co., which operates a deposit of vein graphite 16 miles from this place, made a marked increase in production in 1917. Numerous small veins, the thickest measuring 16 in., have been worked. The veins consist of practically pure graphite, though here and there they contain a little quartz. Most of the veins show bladed crystals of graphite normal to the walls of the vein. More rarely the graphite consists of fibrous material like the best Ceylon grades.

NEVADA

Carson.—The State Mine Inspector, A. J. Stinson, is reported to be enthusiastic about the mining outlook of Nevada. He has recently been inspecting the southern parts of the State. Labor is scarce. Ely is very busy. Eureka, Battle Mountain, Halimton, Mill City, Copper Canyon, Yerington, Las Vegas, and Wonder all have something new to report. Charles Huber, deputy inspector, reports excellent results in western districts.

Goldfield.—Red Hill Florence has 300 tons of ore worth between \$50 and \$70 per ton ready for shipment, which is to be started soon. The 300, 400, and 500-ft. levels are all showing good ore.

Grandma Consolidated's shaft is still in quartz at a depth of 790 ft. Seams in the quartz are said to show zinc by analysis.

Goodsprings.—Yellow Pine Mining Co. pays 6c. per share, equal to \$60,000, on June 15. This makes \$120,000 for the current year. The company took \$25,000 in the third Liberty Loan, making \$100,000 invested in the three loans.

Rochester.—On July 1 Rochester Mines Co. pays its first quarterly dividend of 2c. per share, equal to \$40,000. The mill is treating 190 tons of \$11.50 ore daily.

Virginia City.—The Comstock lode is now producing about \$50,000 of silver and gold per month, nearly all from the north-end group. Last week the Mexican mill treated the following:

Mine	Tons	Value
Con. Virginia	293	\$25.70
Mexican	190	41.85
Sierra Nevada	18	31.96
Union Con.	205	23.72

OKLAHOMA

Picher.—Production of the mining districts last week was 3136 tons of blende and 862 tons lead, valued at \$244,390.

Two years ago there were only a couple of mines in this district, with a few people employed. Now there are 10,000 inhabitants in the town, and over 15,000 in contiguous territory. Over 100 mills are at work within a radius of 1½ miles. In the whole Oklahoma mining region there are 148 mills at work, 40 are under construction, and 25 are planned.

TENNESSEE

Copperhill.—The Tennessee Copper Co. reports as follows for 1917:

An operating profit of \$1,346,082 was made. Of this, interest and depreciation absorbed \$434,833, leaving \$911,149 net. To this is added \$1,717,884, surplus from 1916, making \$2,629,034 available. From this there was taken \$733,631 to cover settlement of sundry claims and losses, leaving \$1,895,403 carried forward to 1918. Current assets total \$3,143,650, and liabilities \$2,661,214. The net bonded indebtedness is \$1,470,099. The reserve for possible liability under the Russian contract in dispute is \$1,140,000.

The general manager, Arthur L. Tuttle, states that 12% of the men employed are in the Army or Navy. Development amounted to 3107 ft. in the Burra Burra, London, and Polk County mines; also 3351 ft. of diamond-drilling. The latter cost \$2.31 per foot. The Burra Burra shaft was re-timbered and overhauled at stations. Sixty-five-pound rails were laid, 6-ton skips installed, and a 3-ton electric locomotive was started on No. 8 level. A new steel head-frame and crusher-house were erected. This mine is in excellent physical condition. Reserves were increased by 498,792 tons. At the London mine compressed air superseded steam for hoisting, etc. The shaft was completed to No. 7 level. Results at the Polk County were not very promising. Reserves in all mines total 3,485,713 tons available, and 255,000 tons broken in stopes. Underground work cost \$1.30493 per ton.

At the smelter new tops were put on three furnaces, a No. 2 Great Falls converter set up, a new sample-mill erected, and flues were repaired. Coke cost \$9.93 per ton, more than double normal prices. There was reduced 671,015 tons of charge, including 457,902 tons of company ore and 39,275 tons of outside ore. Coke used was 6%. Smelting cost \$1.63085 per ton of ore and converting 0.0585c. per pound of copper. Company ore yielded 10,547,708 lb. copper, 59,049 oz. silver, and 197 oz. gold. The cost, including administration, etc., was 16.6c. per pound of fine copper.

The two sulphuric-acid plants made 262,858 tons of 60% acid, against 181,637 tons in 1916. The Hospital, Y. M. C. A., and Commissary Departments did good work.

CANADA

Manitoba

The Pas.—At the Rex gold mine the new mill is in operation, and prospects are fairly good.

British Columbia

Alexo.—The Alexo mine shipped 5790 tons of nickel ore during March. This property is 150 miles north of Sud-

SECTIONS ALONG EAST AND WEST DRIFTS, ALEXO MINE, ONTARIO

bury and 25 miles north-east of Porcupine, on the T. & N. O. railway. The deposit was discovered by Alex Kelso in 1908. Shipments are made to the Mond Nickel Co.'s smelter at Coniston. Development below the 120-ft. level is under way. In the 26th annual report of the Ontario Bureau of Mines the deposit was described by M. B. Baker of Queen's University, Kingston, Ontario.

Cobalt.—Output of the Cobalt district during April is estimated at 1,520,000 oz. of silver.

A fault in the formation at a depth of 500 ft. has been encountered in the Genesee. In small fractures along the fault occurs secondary deposits of calcite containing ruby silver. Keen interest is being taken in the work now proceeding, as this formation appears to indicate the close proximity of a silver-bearing vein. As yet this part of the district has not been productive.

Kirkland Lake.—Erection of a 150-ton mill for the Kirkland Lake Gold Mines has been started.

Sudbury.—A cage-tender at No. 1 mine of the Mond Nickel Co. has been sentenced by the Court to three months in jail plus a fine of \$50 or another month. His trouble was neglect to pull back the chairs in the shaft at No. 11 level. This 2-compartment shaft is 2600 ft. deep, with levels 300 ft. apart. He said he had done this and sent the cage back to No. 12 from an upper level. On reaching No. 11, the cage stopped and 300 ft. of slack wire rope coiled on top and looped over into the adjoining compartment. Meanwhile, over in this compartment a cage with 10 men was being hoisted from the 12th level. After passing No. 11 the rising cage became entangled in the cable which had looped through from the other compartment, and at 100 ft. above No. 11 the coiled cable became taut and the hoisting cable, despite the fact that it had a breaking strain of 67 tons, snapped at a point 40 ft. above the cage. The coiled cable had also coiled around the dogs, preventing the safety-catches from working. At the same time so tightly bound had the cable become that it served as a brake between the dogs and the guides so that the cage merely slid gently back down 200 ft., and there, 200 ft. above the 2600-ft. level, it became wedged. None of the occupants of the cage was injured.

Obituary

Edgar A. Collins died of pneumonia on June 3 at Ben Lomond, California. He had but lately returned from Siberia and had just begun to work with Albert Burch in the investigation of chromite deposits for the U. S. Bureau of Mines. A young and vigorous man, he gave promise of a long and useful career. He was the son of J. H. Collins, a Cornishman of distinction, known as a teacher and investigator far beyond the confines of the 'old county.' His eldest brother, Arthur, was assassinated at Telluride in 1903. Another brother, Henry F., is well known as a writer of a standard book on silver-lead metallurgy. The family has achieved a conspicuously honorable position in the profession. Edgar Collins first made his mark as superintendent of the Combination mine at Goldfield, Nevada, and later as superintendent of the Commonwealth mine, at Pearce, Arizona. Last year he was appointed resident manager for the Ridder mine of the Russo-Asiatic Corporation in the Altai and had barely assumed his new responsibilities when the Bolshevik revolution compelled the cessation of mining operations and his return to the United States. He arrived well and cheerful, ready to undertake new work, preferably patriotic, which was promptly offered to him by Mr. Burch in behalf of the Bureau of Mines. We record his death with the deepest regret, and we know that it will be shared by all that knew him.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

J. M. Nicol has gone to Honduras.

Charles H. Munro and R. F. Lewis have gone to Jarbidge, Nevada.

David T. Day of the U. S. Geological Survey was in San Francisco this week.

D. C. Jackling spent the end of last week at Salt Lake City, on his way to New York.

A. C. Lawson, professor of geology in the University of California, is at Bingham, Utah.

Algernon Del Mar has become manager of the Techaticup mines, El Dorado canyon, Nevada.

R. Itoh and T. Nabeshima, of the Mitsubishi Company, are visiting mines and smelters in the West.

Lucien Eaton, of Ishpeming, has been appointed Captain in the Engineer Officers Reserve Corps.

H. C. Wilmot has left New York for Prescott, Arizona, where he expects to be for several months.

R. T. Walker has been appointed superintendent for the Virginia-Louise Mining Co., at Pioche, Nevada.

Robert Dye has succeeded D. L. Forbes as manager of the Teck-Hughes at Kirkland Lake, Ontario, Canada.

James L. Bruce and B. H. Dosenbach, of the Butte & Superior Mining Co., were at Salt Lake City last week.

H. A. Guess, managing director of the mining department of the A. S. & R. Co., was at Salt Lake City last week.

Edward A. Austin, formerly with the Yukon Gold Co., is superintendent of the Elkoro mine at Jarbidge, Nevada.

F. Le Roi Thurmond has returned to Anchorage, Alaska, from a two months trip examining prospects in Broad Pass.

F. B. Caldwell is working for the U. S. Bureau of Mines, under Albert Burch in the investigation of chromite deposits.

Charles A. Randall has been made assistant to Douglas A. Mutch, general manager for the Dome Lake Mining & Milling Company.

D. W. Brunton is chairman of a committee appointed by the War Department to investigate inventions and devices useful in war.

E. P. Mathewson has been appointed consulting metallurgist to the American Smelting & Refining Co. with headquarters at New York.

R. M. Catlin has received the honorary degree of Doctor of Science at the recent commencement of Rutgers College, New Brunswick, New Jersey.

A. E. Wiggin has been appointed superintendent of reduction department for the Boston & Montana, at Great Falls, Montana, succeeding J. H. Klepinger.

Forest Rutherford, consulting metallurgist, has been appointed a member of the advisory committee on non-ferrous metals to the U. S. Tariff Commission.

Jerome B. Landfield, formerly employed by the Russian government in the capacity of mining engineer, has gone to Washington to advise on Russian affairs.

W. A. Carlyle has taken over the duties (in addition to his own) formerly assigned to E. P. Mathewson with the British America Nickel Corporation, at Sudbury, Canada.

Brent Neville Rickard, metallurgist and assistant superintendent at the Tacoma smelter, of the A. S. & R. Co., passed through San Francisco on his way to Salt Lake City.

J. O. Elton, superintendent of the Anaconda company's electrolytic zinc plant at Great Falls, Montana, is doing special work with the U. S. Bureau of Mines. R. B. Caples takes charge of the plant in his absence.

THE METAL MARKET

METAL PRICES

San Francisco, June 4

Aluminum-dust, large and small lots, cents per lb.	65-70
Antimony (wholesale), cents per pound.....	15
Copper, electrolytic, cents per pound, in carload lots.....	23 1/2
Copper, electrolytic, cents per pound, in small quantities.....	24 1/2
Lead, pig, cents per pound.....	7 1/2-8 1/2
Platinum, Government price, per ounce.....	\$105
Quicksilver, per flask of 75 lb.....	\$110
Spelter, cents per pound.....	9 1/4
Zinc-dust, cents per pound.....	17 1/2

ORE PRICES

June 4

Antimony, 45% metal, f.o.b. California, per unit.....	\$1.10
Chrome, 38% and over, California, per unit.....	\$1.25-\$1.50
Magnesite, crude, California, per ton (nominal price).....	\$7.00-\$8.00
Manganese, domestic, 35 to 54%, f.o.b. South Chicago, per unit.....	\$0.84-\$1.30
Manganese, domestic, 35 to 54%, f.o.b. east of South Chicago, per unit.....	\$0.95-\$1.45
Pyrite, domestic, New York, cents per unit of sulphur.....	28
silica and up to 25%, and bonus of 50c. to \$1 for less than 8 and 5%.....	
Molybdenite, per lb., 90% MoS ₂	\$1.25
Pyrite, domestic, New York, cents per unit of sulphur.....	28
Tungsten, 60% WO ₃ , California, per unit.....	\$24

The U. S. Tariff Commission will hold a conference at the Chamber of Commerce, San Francisco, to which all interested are invited. On June 24, at 10 a.m., the antimony situation is to be discussed; on the 26th, quicksilver; and on the 28th, tungsten. A hearing on tungsten will be held at Denver on the 17th at the New Forest Metal building.

EASTERN METAL MARKET

(By wire from New York)

June 4.—Copper is unchanged. Lead is more active and stronger. Spelter is strong and steady. There is no quotation for platinum.

COPPER

On September 21, 1917, the Government fixed copper prices at 23.50c. per lb. for large lots, and 24.07 1/2 c. for small lots, effective until June 1, 1918. These prices remain in force until August 15, 1918. Quotations in cents per pound are as under:

The advance statement of United States copper production in 1917, by B. S. Butler, has just been issued by the U. S. Geological Survey. The principal figures appear in the New York metal letter on the following page. The domestic consumption was 1,316,463,754 lb., a drop of 113,000,000 lb. Exports totaled 565,000 tons, and imports 278,000 tons.

SILVER

Below are given official (not Government) quotations, in cents per ounce of silver 999 fine. In order to make prompt settlements with smelters and brokers, producers allow a discount from the Government price of \$1, hence the lower price. The Government has not fixed the general market price at \$1, but will pay this price (as from April 23, 1918) for all silver purchased by it. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the current rate of exchange.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound. On May 25, 1918, the Government fixed prices until

September for grade A spelter at 12c. per lb. for itself and the open market. This grade constitutes only a small proportion of the total output. Lower grades can make their own prices as usual. Sheet zinc is fixed at 15c., and plate at 14c. per pound.

Second-grade zinc ore at Joplin, Missouri, was up \$1.50 per ton last week, the rate being \$42.50 to \$47.50.

The Dominion government at Ottawa has ordered the payment of a bounty of 2c. per pound on zinc. This will benefit British Columbian producers considerably.

LEAD

Lead is quoted in cents per pound, New York delivery. Government metal receives 7c. per lb. until August 6.

Lead ore at Joplin, Missouri, last week rose from \$84 to \$85 per ton, basis 80% metal.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. The Government is taking 40% of the United States quicksilver output, paying therefor \$105 per flask. Outside of this business the competitive market can make any price as usual. Prices, in dollars per flask of 75 pounds:

Spot Banca tin is quoted at 99c. on the Pacific Coast, and No. 1 Chinese at 90 cents.

The Llaillagua tin smelter, operating at Arica, Chile, is working on a small scale. Up to April, 30 tons of 99.8% metal had been produced. The plant comprises one reverberatory, one liquatant, and one roasting-furnace, with a monthly capacity of 1000 tons of barilla (concentrate), producing approximately 650 tons of metal. California petroleum residuum is used for fuel. An additional reverberatory and a roasting-furnace are under construction, which will increase the capacity of the plant to 1500 tons of barilla in about two months, at which time the present Llaillagua contract will have expired.

ORES

Antimony: There is no activity, and the market is unchanged at nominal quotations reported recently.

Molybdenite: The market is inactive and nominal at \$1.25 per lb. of MoS₂, in 90% concentrate.

Tungsten: Quotations are unchanged at \$20 to \$24 per unit in 90% concentrate, with only moderate activity. Material containing impurities, but as high as 65% WO₃, has sold at \$24 per unit. Ferro-tungsten is nominal at \$2.25 to \$2.35 per lb. of contained tungsten.

Eastern Metal Market

New York, May 29.

There has been little change in the markets during the past week. They have been only moderately active and price-changes have been insignificant except in tin. The market is firm, however, in nearly all metals.

Copper prices are to remain unchanged officially until August 15.

Tin is being offered a little more freely, and prices are lower.

Lead is fairly active and firmer.

Zinc is quiet, but firm and steady.

Antimony is lower and dull.

In the steel world, the industry is distinctly on a war-basis with almost the entire output subject to Government call. There is, however, a decided rejection of reports of Government preparations to lay hold of the machinery of steel production. There are new Government operations projected on a large scale—two more shipyards and perhaps additional gun plants. Preference is given now absolutely to plates for ships, shell-steel coming second. The advance in freight rates, just announced, will bear heavily on pig-iron and costs of steel, says 'The Iron Age.' With close to five tons of raw material and supplies represented in a ton of steel, the new freight schedule means \$2 to \$3 additional per ton of finished material. About 20,000 tons of shipbuilding material for Japan, in storage on the Pacific Coast, has now been shipped, but licenses have not yet been issued, though expected daily, on the remaining 155,000 tons of the unused tonnage to go in compensation for Japan-built ships.

COPPER

The suspense is over and the market can now settle down to the regular controlled routine which has characterized it for so long, that is, to a Government regulated industry with no market nor speculative features. The relief is due to the fact that the question of a revision of copper prices has been answered by the announcement that the War Industries Board has decided that the present price of 23.50c. per pound for carload and 24.67½c. for less than carloads shall prevail unchanged until August 15. The fact that only 75 days is fixed as the time for a continuance of present levels is regarded by some as a hint or a hope that a revision upward may come then. At least this has been a factor in relieving the disappointment which is and has been keen among many because at least a small advance was confidently expected. The advance statement of the U. S. Geological Survey as to last year's copper production is published. It shows to what extent strikes affected the output last summer. The production of smelters in 1917 was less than in 1916 by over 41,000,000 lb., that of last year having been 1,886,120,721 lb. as compared with 1,927,850,548 lb. in 1916. Refined copper output in 1917 was larger than in 1916 by about 142,000,000 lb. or 2,507,663,067 lb., against 2,362,811,122 lb. in 1916, due to an increased output of electrolytic from foreign copper. Stocks on hand January 1, 1918, were 14,000,000 lb. Both exports and imports made records in 1917, but the apparent consumption in 1917 was less than in 1916 by over 100,000,000 pounds.

TIN

The tin situation has decidedly reversed itself as compared with a short time ago. There were then more buyers than sellers; now there are more sellers than buyers. No longer than about ten days ago future shipments from the

Far East brought 97c. per lb. Today they are down to 88c., and perhaps slightly lower. This is a decline of about 10c. per lb. The market continues quiet, with more metal being offered. Sellers are increasing in number, due to the Banca situation. It is the belief that more metal will soon be available from Batavia, Java, though the actual situation there is clouded. There are reports that ships have sailed, or are about to sail, while in some quarters this is denied. The entire Banca situation is in doubt, but the belief in an easier condition there is stronger, and the market is therefore sagging. Buyers, however, are careful, and are disinclined to act to any extent, so that the business actually done in the last week has been but little. Arrivals at Atlantic ports up to May 27, inclusive, have been 1145 tons. Arrivals at Pacific ports on May 21, 22, and 27 totaled 810 tons. The London market is also lower, with spot Straits quoted at £355 per ton yesterday, or £8 lower than a week ago.

LEAD

The market is daily growing stronger, and inquiry is decidedly more general. One large dealer reports inquiries much more active in the last week than in a month. Sales have also been fairly good. The market is firm and steady at 6.85 to 6.90c., St. Louis, or 7.10c., New York, with that of the American Smelting & Refining Co. unchanged at 7c., New York. Spot lead is held at about 7.25c., New York. *The only feature of the market is the fact that prompt lead is difficult to get, which has been a prevailing characteristic for two or three weeks.

ZINC

It is officially announced that there will be no change in the Government price of 12c. per lb. for grade A zinc after June 1. It is to continue for about 90 days. The prices of 15c. for sheet zinc and 14c. per lb. for plate zinc are also to remain fixed for the same period. The other grades of zinc are left unregulated as heretofore. Prime Western for early delivery is not active, but is firm at 7.25c., St. Louis, and 7.50c., New York, though this has been shaded to 7.20c., St. Louis, in one or two cases. There is very little doing in general, but optimism prevails largely among producers. It is reported that one Western representative of some producers has recently sold July-August-September delivery at 7.30c., St. Louis, but the general quotation is fairly firm at 7.32c., St. Louis, for third quarter.

ANTIMONY

The market is a little lower at 12.25 to 12.50c., New York, duty paid, because of a gradually easier tendency since the fairly large Government buying recently.

ALUMINUM

Both No. 1 virgin metal, 98 to 99% pure, and scrap aluminum, are held at the Government price of 32c. per lb. for 50-ton lots, 32.10c. for 15 to 50 tons and 32.20c. for 1 to 15 tons.

FERRO-MANGANESE

The market is active and fairly large sales are reported at \$250, delivered, for 70% alloy, with \$4 per unit above this standard. The new standard, is being generally accepted. Spiegeleisen is also active, but scarcer than ferro-manganese. Large sales have been made of small lots and lots up to 1000 to 6000 tons at \$70, furnace, for 16 to 18% alloy, with \$3.50 per unit above the 16% standard which is also becoming general. Alloy of 30 to 40% manganese content has sold at \$3.90 per unit.

Company Reports

ALASKA GOLD MINES CO. Alaska Gastineau Mining Co.

Property: large gold mine, mill, and power-plants near Juneau, Alaska.

Operating Officials: B. L. Thane, manager; G. T. Jackson, assistant; D. J. Argall, superintendent of mines; E. V. Daveler, superintendent of mills.

Financial Statement: Alaska Gold now holds \$11,756,100 par value of Alaska Gastineau's \$12,000,000 stock, and \$3,269,000 of its \$3,500,000 bonds.

A comparison of the past two years shows the following:

	1917	1916
Revenue from gold.....	\$2,009,632	\$1,837,291
Sundry income	12,071	37,198
Total receipts	\$2,021,703	\$1,874,489
Operating charges	1,724,474	1,543,908
Extraordinary expenses	26,403
Total expenditure	\$1,750,877	\$1,543,908
Operating profit	270,826	330,581
Interest paid	228,552	217,747

Net income \$42,274 \$112,834

By decreasing the deferred charges account by \$210,853, adding this to the profit for 1917, interest was paid on debentures and notes payable. The latter were reduced from \$650,000 to \$500,000. Current assets were \$896,082 at the end of 1917, a decrease of \$44,946, while deferred charges to operations decreased \$210,853 to \$535,403. Current liabilities are \$763,640, a drop of \$154,858. Reserves for depreciation, etc., remain at \$325,045.

Development: normal operations were hindered by the general labor situation, but broken ore in stopes supplied the deficiency caused thereby. There were only 712 men employed, against 940 in 1916.

Development and prospecting for orebodies was prosecuted as energetically as conditions would permit. A total of 15,472 ft. of drifts, cross-cuts, and raises, and 12,754 ft. of diamond-drilling was completed. The principal object of this work was to find new and richer orebodies in order to maintain the average grade of the ore sent to the mill, and, if possible, to increase the average value. This work was conducted principally in the block of ground between No. 1 and 2 shafts on No. 6, 7, 8, 9, 10, and 13 levels. Its object was the further development of the schist ore-zone which had originally shown good areas and satisfactory value on No. 5 and 10 levels, from which a large tonnage of good ore had been milled; also to further prospect the ore-zone east of No. 2 shaft on its strike toward Sheep creek, and to develop the block of ground between No. 10 and 13 levels west of No. 1 shaft, and finally to do some prospecting on No. 2 vein west of the Alexander cross-cut. The net result of the year's work has shown no new bodies of any consequence east of No. 2 shaft, and has confirmed the work of 1916 relative to the schist body, namely, that its largest areas and best ore were found on No. 10 and 5 levels, diminishing between these two levels in both size and value. An effort was made to find the same schist body in its trend on No. 13 level, without success. Such of this ore as was developed on No. 6, 7, 8, 9, and 10 levels, although of limited quantity, was of much better grade than the average slate ore west of the shaft. Below and in the ground tributary to No. 2 shaft, which extends only to No. 10 level, the principal work done was on No. 11 level with some on No. 12; and although this is still unfinished, indications are that the ore-zone in this block will have a value approximating that milled during the past two years. No

commercial ore was found in development on No. 2 vein west of the Alexander cross-cut, although a cross-cut between No. 1 and 2 veins in the west end of the property indicated possible orebodies to be prospected in the future. Considering only the block of ore between No. 1 and 2 shafts, and from No. 5 and 13 levels, and estimating the value on results obtained from past operations, there would appear to be available for milling in this block some 9,000,000 tons of ore worth approximately \$1.06 per ton. Of this amount 2,357,588 tons is already broken, 2,398,242 tons is prepared for stoping but not broken, and 4,799,487 tons prospected but not prepared. Further prospecting

and development work will be necessary before the exact value and tonnage of this block can be accurately estimated, and the value of the ore sent to the mill from month to month, or year to year, will be dependent upon mining conditions and may or may not approximate the average of the total orebody, depending upon the proportions of ore drawn from different sections of the mine. No change to advantage has been indicated in the system of mining originally adopted, and thereafter up to the present employed.

Production: the past two years compare as under:

	1917	1916
Ore milled, tons	2,240,346	1,892,788
Average per ton	\$1.103	\$1.193
Tailing, per ton	0.206	0.222
Extraction, per cent	81.32	81.33
Costs, per ton:		
Mining	\$0.42285	\$0.38412
Milling	0.26026	0.26881
Shipping and smelting concen-		
trate	0.03522	0.03297
General	0.05141	0.12978
Total	\$0.76974	\$0.81568

So far as costs are concerned, D. C. Jackling says that operations have proved that the original estimates were more than ample.

GOLDFIELD CONSOLIDATED MINES CO.

Property: gold mines and 100-stamp mill and treatment plant at Goldfield, Nevada.

Operating Officials: J. W. Hutchinson, general manager; J. B. Kendall, mine superintendent; Earle W. Hart, mill superintendent; R. H. McLoughlin, chief engineer; H. N. Witt, geologist; B. B. Beckett, electrical engineer; E. M. Moore, purchasing agent; R. J. Davey, cashier; and E. A. Julian, engineer in charge of exploration department. J. W. Hutchinson and J. B. Kendall recently resigned.

Financial Statement: during 1917 sales of bullion realized \$1,439,716, plus \$290,454 for sales of sundry mill products and \$26,765 for other earnings. Deducting \$85,649 paid for ore purchased and lessees, the total was \$1,671,285. Operating expenses amounted to \$1,493,519, less \$68,134 for exploration charges. Adding interest, etc., the net profit was \$128,501. Balance at start and end of year remained at \$1,183,763. As the property has no great future, assets

were valued, giving a total of \$2,331,000. Six years will be required to realize this amount. On the 3,559,148 shares issued this is equal to 65½c. per share.

Dividends: none were paid in 1917, so the total remains at \$28,999,832, or \$8.15 per share.

Development: In August last the ore exposed underground became unprofitable. Ore-reserves and dumps at all the company's mines on Jan. 1, 1918, contained a total of 125,000 tons. At least double that quantity is expected to be milled before operations cease.

There are now 40 sets of lessees at work, employing 80 men, in certain sections of the Clermont, Grizzly Bear, Combination, Mohawk, Red Top, and Laguna mines. Last year they mined 14,770 tons of ore assaying \$14.75 per ton. Their net return from the company was \$82,237, out of which they paid for labor and explosives. All underground work cost \$2.78 per ton.

The Exploration Department investigated 696 properties, and examined 45. Option on the Lampa mine in Peru was given up. In February 1917 an option was taken on Montana Mines Co.'s property in Santa Cruz county, Arizona. Ore developed amounted to 30,000 tons, assaying 12% zinc, 6% lead, and 6 oz. silver per ton. Exploration at depth shows that the vein weakens. The mine is not to be purchased. A concentrating mill is in operation. The Ash Peak mine in Greenlee county, Arizona, was also taken under option. A silver-bearing quartz vein of unusual persistence was opened to depth of 500 ft., and is increasing in value with depth. In Butte county, California, the Surcease gold mine is being opened under option. A shallow adit shows 5 ft. of \$12 ore over a length of 100 ft. Deeper work is in progress. Some claims near Hazelton, British Columbia, are being prospected.

Production: the mill treated 250,550 tons of ore averaging \$8.14 per ton, also 81,835 tons of old tailing assaying \$1.27 per ton. Of the ore, 66% was treated by cyanidation and 33% by flotation. It was found advisable to sell concentrate from the flotation plant. Reserves of tailing are estimated at 1,800,000 tons, averaging \$1.50 per ton. From this should be extracted \$1, less 60c. cost, making total profit of \$720,000. Production to date is 3,094,353 tons of ore assaying \$23.40 per ton gross, equal to \$72,393,065. The mill has treated 2,874,622 tons, yielding \$51,200,817.

Costs: during 1917 these totaled \$6.32 per ton; \$2.78 being for mining, \$2.41 for treatment, 44c. for general, and 36c. for marketing. The average cost for 9 years is \$6.81 per ton. Increase of 1917 over 1916 was 83c. per ton.

VINDICATOR CONSOLIDATED GOLD MINING CO.

Property: gold mines and works at Cripple Creek, Colorado.

Operating Officials: W. E. Ryan, general superintendent; Louis S. Noble, consulting engineer.

Financial Statement: ore sales and royalties (\$153,683) from lessees totaled \$896,621 in 1917, plus \$17,503 from sundries. Operations cost \$717,775, leaving a profit of \$196,348.

Dividends: four quarterlies absorbed \$180,000, equal to 12%. This makes \$3,712,500 to the end of 1917.

Development: new openings amounted to 10,327 ft., lessees doing 5515 ft. The total to date is 255,434 ft. Exploration did not reveal material additions to ore-reserves, which are estimated as 255,500 tons. In a caved area adjacent to the Golden Cycle shaft there is a large tonnage available. On No. 20 level of this shaft and No. 19 of the Vindicator there was nothing new developed.

Production: 39,799 tons of company ore valued at \$973,537, and 47,119 tons of lessees' ore worth \$716,804. Freight and treatment on these cost \$480,156. To produce the 39,799 tons there was mined 205,691 tons. Crude ore is

sized, washed, and sorted into shipping ore, that suitable for the flotation plant, and waste. Cost of flotation is higher than expected, but results are satisfactory.

BEAVER CONSOLIDATED MINES, LTD.

Property: silver mine and mill at Cobalt, also gold mine at Kirkland Lake, Ontario.

Financial Statement: during the year ended February 28, 1918, ore and bullion sales, etc., realized \$354,341. Operations cost \$247,044. Cash on hand at March 1, 1917, was \$151,890, against \$15,701 a year later. Kirkland Lake Gold Mining Co.'s shares purchased cost \$310,242. Profit and loss balance at credit amounts to \$744,276.

Development: at Cobalt 4952 ft. of new work was done, including 75 ft. of sinking a winze below 1600 ft. A new orebody was opened on the 530, 600, and 700-ft. levels. To a depth of 67 ft. below the 1600-ft. level below the diabase sill in Keewatin formation mill ore has been opened, also to 147 ft. above the level.

At Kirkland Lake, 4590 ft. of work was performed. No. 2 shaft was sunk to 700 ft. A new main shaft is being sunk. Good ore was found on all levels save No. 2. Reserves are estimated as worth \$700,000. A 150-ton mill is under erection, while a hoist, compressor, and power-plant were completed.

Production: the plant worked 310 days, extracting 372,973 oz. of silver.

HEDLEY GOLD MINING CO.

Property: the Nickel Plate and Sunnyside mines, 40-stamp mill, cyanide works, and 1800-hp. hydro-electric power-plant at Hedley, British Columbia.

Operating Official: Gomer P. Jones, general superintendent.

Financial Statement: the net profit in 1917 was \$238,095, out of \$737,840 received for gold extracted. Surplus on January 1, 1917, was \$443,688, and that of a year later \$441,783.

Dividends: four absorbed \$240,000.

Development: 1030 ft. of new openings were made, also 3766 ft. of diamond-drilling. The Dickson incline is down 970 ft. All stopes from No. 3 to the 900-ft. level, about 1400 ft. of stoping ground, are of normal grade. Drilling indicates better ore at 900 ft. Reserves consist of 313,000 tons of \$10.01, and 87,650 tons of \$6 ore.

Production: the works treated 71,207 tons of \$11.29 ore, at a cost, including all expenditures, of about \$7 per ton.

The cheap power derived from the hydro-electric works will enable operations to continue, in spite of taxes and other charges.

CERRO DE PASCO COPPER CORPORATION

Property: all of the mining properties and other assets of the Cerro de Pasco Mining Co., and Morococha Mining Co., which companies were dissolved in 1917. The corporation also controls the Cerro de Pasco Railway Company.

Financial Statement: in 1917, sales of metals and ore realized \$24,974,082, inventory \$3,927,955, dividends \$1,091,764, and sundry revenue \$188,715, a total of \$30,182,515. Operations cost \$7,832,006, custom ores \$5,342,394, taxes \$1,207,822, reserve funds \$7,039,175, and inventory \$3,147,520. The profit was \$5,613,598. The balance on Jan. 1, 1917, was \$187,552, and a year later \$11,447,916, the surplus from subsidiaries being included.

Earnings of the railway were \$1,043,090, of which \$350,519 was profit. Balances were \$1,281,156 at beginning of the year and \$1,147,175 at the end. One dividend absorbed \$484,500.

Dividends: four, each with an extra, totaled \$4,009,471. During 1917 the mine and smelter operated satisfactorily.

EDITORIAL

CANTIGNY is followed by Château Thierry. Our boys at the front are doing as the Allies hoped and as we expected. The stars in Old Glory are shining as never before!

ONE hundred scholarships are to be established in American colleges for French women. The gift has been accepted by the universities of France. We hope that the ladies will remain here after they finish their post-graduate courses and marry our sons, for they represent a stock that will enrich the racial heritage of America. The mothers of France have proved themselves of heroic mould and it is from them that their sons have drawn inspiration in the crisis of their fate.

THE new schedule of prices for domestic manganese ore will be found summarized on our Metal Page this week. This was arranged by the American Iron & Steel Institute, and was approved by the War Industries Board, taking effect after May 28. Briefly, from 86 cents to \$1.30 per unit will be paid for ore containing from 35 to 54% metallizable manganese, with premiums and penalties for silica under and over 8%. The prices are somewhat higher than those prevailing during the past few months.

CONSOLIDATION of the express companies with a view to more economical administration is a good thing. Now that they are to operate under Government control, they will, let us hope, show a better code of conduct, even at the cost of more red tape. The unprincipled manner in which charges have been collected at both ends, especially on presents, is a blot on the records of these common carriers and it is one that the citizen is warranted in resenting bitterly, as we do, having been victimized on several occasions.

SHIPPING facilities are utterly inadequate for transporting materials from the West, and no remedy seems to be possible at this time. In our last issue Mr. E. H. Wedekind suggested that California pyrite might be sent to the Atlantic seaboard as ballast, but the U. S. Shipping Board informs us that orders from Washington require the loading of all vessels with grain and other food-stuffs that are sufficiently heavy to obviate the necessity of using ballast. The only exception relates to ships that are occasionally dispatched to Chile for

cargoes of nitrate. These sometimes go partly laden, despite the demand for lumber and manufactured articles in that country. The need of nitrate is so urgent that the Government is not willing to allow time for the loading and unloading of other cargo. The ships take on the nitrate at Chilean ports for Atlantic coast points and do not return. Practically no vessels come from the East at the present time. California could supply large quantities of pyrite and alum, if means of transportation were available.

PESOS are not being issued by the Mexican mint, and practically none are in circulation. All the silver now being coined in that country is made into fractional currency, on which a larger profit accrues to the Treasury because of its lower fineness. All the local mints have been closed, and coinage is done at Mexico City only. The result is that no favorable markets exist for the output from the smaller mines. The cost of transporting bullion to Mexico City, for example, from the West Coast, is so great as to be practically prohibitive, and no insurance can be obtained. The result is to force the producers either to ship to the United States at considerable cost and inconvenience, or to sell at a heavy discount from the market value to commercial houses, most of which are controlled by Germans.

GOLD production of Australia continues to decline. Figures to hand for the first quarter of 1918 show a total of 319,518 ounces, against 364,613 ounces in the same period of last year. Two well-known producers were shut-down recently, namely, the Great Fingall in Western Australia, which has yielded gold worth \$24,000,000 from 2,000,000 tons of ore since 1892, and paid \$5,900,000 in dividends; and the Scottish Gympie in Queensland, which, for some time past has been trying to make ends meet by treating \$4 ore. This company has paid \$3,000,000 in dividends. The principal factor against profitable gold mining in the Commonwealth is the abnormal expenditure on supplies, the cost of which has risen more rapidly in Australia than in other parts of the world.

ADVERTISEMENTS in the local press, by the United States Platinum Company, through a Boston brokerage firm, offer stock in an enterprise formed to exploit a platinum deposit in the Grand Canyon of Arizona. This

deposit is said to be "the only commercial" one in the country and is stated to contain "millions of tons in sight." We have read the prospectus and made enquiries, all of which prompt us to caution the public. The name of Mr. J. M. Boutwell, formerly of the U. S. Geological Survey, is used to substantiate sundry optimistic assertions, and samples taken by him are quoted, showing as much as 2.4 ounces of platinum per ton. Mr. Boutwell's report is not given. We shall be glad to hear from him in confirmation, or in correction, of the statements imputed to him. The prospectus states that there are "millions and millions of tons actually in sight" that "greatly exceed the lowest average sample (\$33.91 per ton)." We regret to see an honorable name attached to a scheme apparently so questionable.

OPERATORS of mines in Utah have taken steps to protest against the increase in railroad freight-rates, amounting to 25%. A telegram has been sent to Mr. McAdoo, Director-General of Railroads, explaining that such an increase in the cost of transport will hinder the production of the low-grade fluxing ores needed for smelting and cause the shutting-down of many mines. From Colorado likewise we hear that this increased burden to be placed upon the mining industry is viewed with consternation in a region where so much of the output goes to the smelters and therefore is dependent largely upon low freight-rates. At this time when the waging of a great war calls for an intensive production of metals and minerals, it is a blunder, we suggest, to do anything likely to diminish the necessary supply. This is no time to make a good showing for the railroad administration at the expense of an essential industry.

AWARD of the principal prize given by the School of Journalism in Columbia University has fallen to the New York 'Times' "for the most disinterested and meritorious public service rendered by any American newspaper during the year, in having published so many official reports, documents, and speeches by European statesmen relating to the progress and conduct of the War." This award, and the terms of it, will gratify many of our readers, fully aware of the splendid work that 'The Times' has done in behalf of the national cause. It sheds lustre on the school endowed by Pulitzer, who, like many others, left a large sum of money at his death to undo some of the harm that he had done during his life, for Pulitzer, with 'The World,' started the streak of yellow journalism that Hearst has widened and extended across this continent. This type of journalism is shamed daily by a paper like 'The Times,' which we regard as the greatest newspaper in the language, superior to its namesake in London, now degraded by the unscrupulous commercialism and blatant egotism of Lord Northcliffe, formerly Alfred Harmsworth.

GREAT BRITAIN, by its Board of Trade, has entered into a contract with Australia, represented by the Zinc Producers Association, whereby the whole output of Australian zinc concentrate is to be bought by the

British government for the period of the War and ten years afterward. The entire stock of zinc concentrate existing at the end of last year has been taken over. The contract specifies that a maximum of 250,000 tons per annum is to be purchased during the War and for one year thereafter, whereas 300,000 tons is to be the maximum annual purchase for the subsequent nine years. This zinc concentrate comes almost wholly from the Broken Hill district. Before the War, Great Britain consumed 200,000 tons of zinc and smelted only 55,000 tons. Broken Hill was producing a quantity of zinc just equal to the British consumption, yet the bulk of the shipments of concentrate coming from Australia passed up the English channel to Rotterdam, Antwerp, and Hamburg, to be smelted in Belgium or Rhenish Prussia, mostly on German account. The establishment of a British domestic control of Australian production is a result that will profoundly affect Germany's economic status after the War.

NO more pathetically untruthful head-line has appeared in our local organs of misinformation than the one that was flaunted in one of Hearst's papers a few days ago. 'Russia Mobilizes,' it said. We happen to have seen, and talked with, half a dozen mining engineers recently returning from Russia and Siberia. They unite in saying that the Russians have "quit," they are "all in," they are just "lying down," utterly sick, disgusted, and weary of the fighting, for which they have been so poorly prepared and so badly organized. If ever a great people went to pieces and lay down its arms in abject surrender, it is the supposedly new democracy of Eastern Europe. At present it is as much like a democracy as a mob is like an army. Russia is showing how badly the forms of representative government are suited to a people 80% of which is uneducated; it is also showing the contrast between the highly organized military rule of the Prussian and the chaos of complete anarchy. We must be patient with the Russians—yes—but we must not delude ourselves into the belief that any help can come from that quarter in the completion of the great task the Allies have in hand. Russia is waving not only the red, but the white flag also. It will be fortunate if the War ends before the Germans can utilize the resources that they now control in Russia.

SMELTING operations at the Grand Forks plant of the Granby Consolidated Smelting, Mining & Power Company are described admirably by Mr. Walter B. Bishop in a short article in this issue. Mr. Bishop is superintendent of the plant he describes. We are grateful to him for writing an article so much to the point and so carefully prepared. Our readers are aware of the fact that the Granby Consolidated is an American enterprise that can claim to be operating the biggest copper mine in the British empire. The mine at Phoenix and the smelter at Grand Forks, both in the Boundary region of British Columbia, have become relatively old and decadent—as an industry, not technically—but this company is now operating the Hidden Creek mine and

smelter near Anyox, upon Observatory inlet, on the coast of British Columbia, close to the Alaskan boundary, 600 miles north of Vancouver. The Hidden Creek property was acquired six years ago; last year it produced 760,705 tons, the total output of the Granby company in 1917 having been 1,490,804 tons, yielding 37,676,368 pounds of copper, as against the 671,990 tons, yielding 16,357,329 pounds of copper, produced by the Britannia mine, on Howe Sound. The Hidden Creek mine has a reserve of 18,139,163 tons averaging 1.61% in copper, whereas the total reserves of the Granby company are estimated at 23,193,581 tons in six different mines, of which three are in Alaska and three in British Columbia.

WITHOUT undertaking to criticize at this time, it is important to direct attention to a report of the British Committee on Trade After the War. Whether peace be near or remote, it strengthens the national resolve to work constructively upon plans for the future. An ideal crystallized in a feasible program is worth far more as a thing to fight for than an ideal floating in the haze of abstract theory. The British Committee, following lines of reasoning similar to those we have presented heretofore in these columns, opposes an attempt to apply the boycott, declaring it impracticable and inexpedient. The fact that any plan for a reconstructed world must consider the special difficulties of a transitional period is clearly stated. The Paris resolution is still made the basis for the economic outlook, and that involves trade discriminations in favor of the Allies, with the frank acceptance of a protectionist policy. It is further proposed that no raw materials, such as iron, coal, tungsten, glass, thorium, nitrates, barytes, and the like, shall be allowed to enter the territory of the countries with whom we are now at war, for a considerable period after the return of peace, and control over the industries in which these supplies are used is recommended through the medium of export duties in the countries of origin. These suggestions point toward a line of thought that prevails also on this side of the Atlantic. They are far from being practical, but they have the merit of seeking in the economic relations between the nations for a satisfactory basis on which to re-organize the world.

The Human Side of Engineering

It is with keen pleasure that we publish the address delivered by Mr. James F. Kemp at the recent commencement exercises of the Missouri School of Mines. Our friend, until lately the professor of geology in Columbia University, is the right man to discuss the subject selected by him for the occasion; if anybody has an intelligent sympathy for the workers of the world, whether they work chiefly with hand or brain, he is the man, as his former students can testify. 'Uncle Jim' is no pedantic high-brow or academic cynic; to him nothing human is alien; to him the relations between capital and labor present aspects touched with the red blood of live men. He told the graduates at Rolla to make a serious effort to appreciate the obligations, as well as the rights,

of citizens in a democracy, and more particularly the duty of educated men toward the uneducated, of employers to employees. We like his mention of the humane spirit shown by such managers as Messrs. Hjalmar Lundblom, E. P. Mathewson, and Stanley A. Easton. Generalizations are never as convincing as concrete examples, and it is well that recognition should be given publicly to those that set a good example. Much remains to be done in behalf of the toiler underground and aboveground; the 'safety first' movement has been developed to high efficiency, but there is a 'safety first' of citizenship that looks to the safeguarding also of a man's spiritual needs. Let us, by all means, protect the industrial worker from the accidents incidental to his occupation, but let us also protect him from the dangers inherent in the crudities of a poorly organized community as well as the alienation inseparable from the segregation of hordes of foreigners. The great task of Americanization faces us today as never before. If the American people are to be fused into a self-conscious nation, we must see to it that the heterogeneous fragments of Europe are assimilated, otherwise this country as a body politic will continue chronically dyspeptic. Mr. Kemp offers several excellent suggestions for accomplishing this purpose. The club-house is a dissolver of unlikenesses and incongruities; it is a means for bringing diverse elements into harmonizing relationship, but it must suggest no idea of patronage. For that reason we commend the useful offices of the Y. M. C. A., or some such scheme as Mr. Albert Burch carried out at Plymouth, where the club-house, built by the Plymouth Consolidated Gold Mines, Ltd., was passed by the company to the control of a committee representing the town and the mine, through representatives elected from the townspeople and from the company's staff. Such a club, so administered, brings the members of the entire community into sympathetic touch and promotes friendly relations between the national and the foreigner. The latter will remain 'foreign' until he understands American ideas, and these he never will understand until he knows our language. A nation is a people speaking the same language and having common traditions. The traditions are the consequence of the language. Therefore the primary step in nation-making is the uniform knowledge and general use of a single language. As soon as club-houses are built, it should be practicable to arrange for classes in English at which aliens should be invited and persuaded to attend. Let it be noted that "aliens" includes those already naturalized if unable to speak English fluently and to read the national language readily, for any man that thinks in a foreign language continues alien, despite all the papers he may sign and the oaths of allegiance he may take. Language colors the mind and tinges the thought; it delivers to us the racial heritage that it has guarded and sanctified. We have a language made glorious by the flowers of an ancient and noble literature, by Shakespeare and Milton, by Chaucer and Addison, but also by one born in later times, by one that used English with the simplicity of a child, the per-

fection of an artist, the profundity of a sage—Abraham Lincoln. Let his language be the speech of every man living in the United States.

Conserving Technical Men

When we witnessed the first rush of our brave college-boys to serve, and to save their country from invasion, we rejoiced; it proved that the spirit of weak surrender, which had been preached so long in our midst, had not destroyed the manhood of the rising generation. These youths represented the finest product of American culture, and were the sons of families in which both intellectual and moral ideals are perpetuated. We were doing, therefore, the most superbly democratic thing that could be done; we were sending the flower of our civilization to mingle with those less favored by circumstance in common devotion to the great cause of Country and Freedom. This was building for a future that was to be enriched with sympathetic understanding between men of every walk in life, men who should ever after be linked by subtle bonds forged in the heat of an unspeakable inferno. It was glorious to witness this immolation of our college men . . . *pro patria!* Then we reflected that a large proportion of these splendid youths represented the Nation's hope for a continuance of the work of technical detail in making and keeping ready for the great struggle before us, and for the days to come. We sounded a warning; these men could not be spared from the urgent business of using science to overcome the Enemy, who, above all things else, applies science to his work of destruction. The empiricist, suddenly and but partly trained, can never replace those grounded, as are the young men from our colleges, in the fundamentals of technology. The result would be rapid deterioration of the work done behind the lines, inferiority of equipment at the front, and the risk of disaster for us all. The appeal to restrain these technical students became general, and the War Department issued orders putting it within the power of such as might show appropriate standing in their studies to elect an assignment to continue their studies until they should have completed their academic training. This, however, has proved ineffective. The spirit of sacrifice has been re-born in America, and our young men will not exercise an option to which the slightest color of 'slacking' can be given. They still desert the laboratory and the lecture-room for the daring exploits of soldiers active in a kind of defence the reality and the heroism of which all can understand. The threatened shortage of men to command the chemical factories, the steel plants, the copper refineries, the electrical works, has become so alarming that the Engineering Council has passed resolutions that should encourage the Administration to take prompt action. This is urgently needed at the present moment, when the colleges and universities are closing for the summer. It is a time when under-classmen are most likely to enlist. The problem can be met only in the manner suggested; young men now in the course of technical

training, and showing aptitude for their work, must receive orders to persist until such time as a change of policy might seem desirable.

A Message From the Front

Messages from our soldiers are becoming numerous; they are always read with keen interest and deep respect. We that stay at home take off our hats, mentally, every time they speak to us from the bottom of their hearts, as does a captain in one of our engineer regiments in this issue. We give his letter verbatim. He emphasizes the fact that this war is a colossal engineering enterprise, which therefore must be conducted on scientific principles, with eyes wide open and every faculty keenly alert; whatever the high principles and lofty ideals that stimulate the Allied peoples, the operations themselves must be actuated by the "cold, non-sentimental, non-hysterical, non-optimistic, non-pessimistic facts of science." The Enemy must be beaten, otherwise there is no hope of a world such as it is the dream of our civilization to make and to continue. We shall abstain from further comment, for our gallant friend at the front speaks beyond the need of interpretation. There is this to be said, however: between the men in the trenches and those remaining at home there is an experience that has given them a vision of life utterly unlike our own. In the current 'Atlantia Monthly,' Mr. Willard L. Sperry has written on 'The Gulf' that divides the combatant from the civilian. The letters from the men now facing death hourly in the trenches breathe a fineness of spirit and a prematurity of wisdom, in its highest sense, that are wonderful. They have descended into hell and have risen again glorified. They are different men now—not the careless youths or the irresponsible youngsters that left home cheerfully to perform a compelling duty, but prematurely sagacious and serious, fired by chivalric emotions beyond our ken, touched by a divine accolade. Despite their frequent and affectionate messages we recognize a curious reticence, a brooding over the ineffable, a background of experience that they can share only with their comrades—in silences more eloquent than words. It remains for us to endeavor to keep in touch with them, and appreciate "war's obscene blasphemy against life," to realize that "an army does not live by munitions alone, but also by fellowship in a moral purpose." If from this hideous calamity we are to extract the good that is in things evil, if we are not to be sundered in sympathy from the men that are doing the biggest thing in the world today, we must do our utmost to win some comprehension of their point of view, their new aspect of life, their new vision of the great realities. Therefore we ask those on the firing-line to write occasionally for publication in our pages, thereby creating and maintaining the links that may hold us together for the work that must be done to reconstruct industry after the War and to so cement the bonds of nationality that the American people may be unified as never before.

DISCUSSION

Man-Power

The Editor:

Sir—At the bottom of the able address on 'Man-Power', given at Boston, by J. Parke Channing, which address was reproduced from the *Trans. A. I. M. E.*, in the *MINING AND SCIENTIFIC PRESS* on June 1, lies the concept of individualism as a necessary factor in the proper development of mankind. This is opposed to collectivism, which commonly is advocated as a means for equalizing social and economic conditions. Mr. Channing insists wisely upon a broader training of engineers in the humanities, which is equivalent to preparing them to understand men not as if each were a single phenomenon, but as expressive of psychological laws, whether we consider men individually or in their group relations. Fundamentally this rests on biology. It is more than psychology, for it relates to man as we actually find him, that is, in a state of change, subject both to group and to individual variation. Whether Mr. Channing meant precisely this, I believe it is fair to put such a construction upon his interesting argument. The failure to recognize this flux in mental development is a part of the cause of the persistent misunderstanding between the classes, which has been intensified since the factory system began its process of segregation of workers. Occupational differentiation, with its corresponding social classification, finally extended even to the United States, which had enjoyed a period of such liberalizing individualistic effort during the first 70 years of its existence as to seem for a time to confirm the philosophy of the Declaration of Independence in declaring all men to be created equal. Anyone who turns away from the consideration of these problems of creative evolution, on the assumption that they are merely academic, has failed to grasp the significance of the great social question which Mr. Channing so clearly recognizes as an impending legacy of trouble from the present War. His citation of the revolutionary program, recently announced by the British Labor Party, affords justification for his contention that engineers should be specially trained to deal intelligently with the man-power that is beneath and above the highest achievements of this mechanical age. I am impelled to extend the consideration of these questions, partly by reason of Mr. Channing's pleasant mention of a statement contained in my recent discussion of the economic basis of peace-compacts in the '*Atlantic Monthly*'. It is true that the conclusion there reached, following a process of cold analysis of the leading causes of international friction, led inevitably to the recognition

of free trade as the single road to enduring peace and persistent progress. To that extent, as Mr. Channing observes, I affirmed what the British Labor Party has more recently announced as the prime essential for world peace, but I also showed that free trade, suddenly adopted by any nation, would be the equivalent, for that nation, of committing suicide. I pointed out that free trade, rightly understood, meant non-protectionism, which is a far broader and more complex thing than the mere demolition of tariff walls. I might have gone still further, and have shown that the sudden introduction of the principle of non-protectionism throughout the world would result in the complete subjugation of those nations having the higher standard of living to the economic yoke of the nation that possessed the greatest comparative advantage in natural resources, geographic position, moderate labor cost, and effectiveness in both man and machine-power. The proclamation by international treaty of simple freedom of trade, without simultaneously striking at the subtler and more powerful schemes for protection, would be to deliver ourselves and our posterity into the hands of the conscienceless domineering Germans. The ideal of pan-Germany would then be easy to realize, making Mittel-Europa the purveyor to an outer world enslaved in economic bondage. This is what, in its blindness, the British Labor Party would inflict upon us all, if its socialistic plan were to be adopted as a universal rule. It is important to discriminate sharply between the constructive doctrines of rational social progress that are often preached by socialistic propagandists, and the principles destructive of individual initiative, which ever lurk in these programs. Social evolution and socialism are two wholly different things. We should distinguish between them, even in our nomenclature, in order to avoid confusion. One may hold advanced ideas concerning government ownership of public utilities; he may approve of the regulation of industry and the fixing of relations between labor and production, under a system that denies to men much of the assumed right to do altogether as they like with their own, and yet be at the antipodes from accepting the administrative absolutism that is involved in the schemes of the socialists. We might call the true civic reformers, who advocate the free play of social evolution, by the distinctive name of political scientists, so that they might preach progress without fear of being classed with the socialists whose fundamental concept, in whatever garb it may be masked, is the subjection of the individual to bureaucratic initiative. As an example, the very program of basic aims announced by the British Labor Party, and

cited by Mr. Channing as symptomatic of an attitude of mind that must be understood in order skilfully to combat its influence in a constructive manner by the progressive leaders of industry, is as good an illustration as any. The British laborites claimed to analyze the needs of society, and declared that the civic 'house' stood upon four pillars: the first was the national minimum, and this consisted of a minimum wage, a minimum period of labor, a minimum of leisure, a minimum provision for health, a minimum of education, and a minimum of subsistence; the second pillar was the democratic control of industry; the third was a revolution in finance, signifying virtual nationalization of all property, which in its effect upon private holdings is the same thing as confiscation; and the fourth was the diversion of the surplus wealth to the common good. What is the matter with that program? One defect in it is that it fails to represent an ultimate analysis. The principle of democratic control of industry, according to the exposition given in the document, necessitates "a genuinely scientific re-organization of the nation's industry, no longer deflected by individual profiteering, on the basis of common ownership of the means of production (and) the equitable sharing of the proceeds among all who participate in any capacity." If this were done the fourth pillar would be demolished, since there would be no surplus wealth to be diverted to the common good after the proceeds of industry already had been shared equitably among the participants. The third pillar is concerned with taxation, and is part of the system for holding industry manacled under democratic or state control. The British Labor program, therefore, reduces to the single demand for democratic control, with the national minimum introduced as a corollary. In other words, the individual would surrender his freedom of action to bureaucratic administration under an elective absolutism. There is but one pillar left; all the rest relates to the details for carrying out the restriction of the individual initiative to the will of a governing few.

About the same time that this program was issued, the French socialists held a convention and published a proclamation showing a divergent and more conservative opinion, consistent with the spirit of the French, who are the arch individualists of the age. Their program strips off the detail that clutters and obscures the issue as presented by the British laborites; the single trace of internationalism is the demand for a world-wide agreement fixing hours of labor. That strikes a note of universality because it would tend toward equalizing the conditions of competition. It is a broadly constructive idea, worthy of serious thought, squarely presenting one factor that must concern us in any scheme for universal harmony that is to prove effective in the normal progress of the nations. We must keep in mind that true national and racial advancement consists in developing highly evolved individuals, consciously reaching after the creative intelligence. Moreover, there lies in this French program the germ of the principle that must be cultivated in attaining the ideal basis of world democracy. It presupposes a gradual uplift of men in their economic

relations; a gradual elevation of the human standard; and necessarily this involves economic tutelage through a disciplinary tariff destined to disappear automatically when the higher level of the workers in any industry is reached. The problem of an equalizing tariff is the most attractive for working out a practical basis for conserving the best in the development of the past and for lifting a re-constructed world toward a higher plane that I have been able to conceive. I have stated here no more than the fundamental conception; the elaboration of the detail into a consistent plan is a matter requiring larger space. It will be evident, however, that it is based on the idea of conserving and utilizing a highly developed manpower as the most vital essential in social progress.

Simplified Price-Level Economics

The Editor:

Sir—Under this caption Richard Hoadley Tingley, in your issue of May 4, discusses some economic principles and arrives at some conclusions which appear in part to be open to grave question. Mr. Tingley deprecates the "quantity of money" theory, and also the influence of "rapidity of circulation." They "may be well enough for the class-room" or as "good mental gymnastics," he says. In this I must disagree with him. If these theories are wrong they are not fit for the class-room, nor can they be said to be "good mental gymnastics."

One of the points at which agreement is found with Mr. Tingley is on the influence of goods, this service, to my mind, however, needing definition. That a shortage of goods usually increases the price of such goods is, of course, obvious, and hardly requires discussion.

Let us then consider the money question. We will suppose the supply of goods to remain constant but the amount of money in a given community to be doubled. To be definite, let us assume every family to have, normally, an income of five dollars per day, and say that each can live comfortably on that amount, but consuming it all. Now we will suppose the income of every family in the community to have been doubled, and that each now receives \$10 per day. What will be the result? The members composing these families will have better food, more clothes, automobiles, confectionery, and there will be better homes and more waste, in short, an increased consumption. This must result in a decrease in the quantity of goods which we have supposed, for the sake of argument, to remain constant, but which actually cannot remain constant under the greatly increased consumption. Hence will follow a shortage of goods and a natural rise in price, which is directly traceable to the increase in the quantity of money.

The 'rapidity of circulation' theory may be illustrated easily by a variation in the foregoing example. Suppose the increase of \$5 is not spent at all, and is promptly removed from circulation. This does not mean deposited in banks whereby it gets back into circulation, but hid-

den away, for example, in the time-honored stocking or in the hole in the ground. In this case there will be no increase in prices, and goods along with prices can remain constant. That everyone has more money is obvious, but as this money, by the assumed conditions, has lost speed of circulation coincident with its appearance, no economic effect becomes evident. If, however, people after a time begin to spend this money, namely, give it speed of circulation, there will be a depletion of goods, just as occurred in our example of the increase in the quantity of money. Thus we see that quantity of money and rapidity of circulation are real factors, and that the statement that gold and currency have nothing to do with it is open to serious question.

One of the greatest difficulties in the study of economics lies in comprehending just what money is. The difficulty, probably, is not inherent in the subject itself, but lies in the fact that from our earliest childhood we have absorbed one-sided impressions in monetary matters. From the first we have seen small coins exerting an apparently disproportionate power, while little slips of engraved paper accomplished still greater wonders. We have understood nothing of the real reasons why these little coins and slips of paper are so potent. We did not, and perhaps do not yet realize, that coins are made of gold and silver in order that they may contain intrinsic value; that they are made of definite alloys, in definite sizes and weights, fashioned and stamped with edges milled so that mutilation becomes immediately evident. In short, the coin is a commodity, accurately stamped, weighed, and tagged in order that all may readily know its worth. This analysis teaches us that this mysterious substance is after all but a commodity; and that the slips of paper, when closely examined, are but promises to deliver a specified amount of this accurately standardized commodity. Once having determined that money is in essence a commodity, it is to be expected that the laws of supply and demand apply to money as to other commodities, and as an abundance of wheat tends to cheapen wheat, so will an abundance of money tend to cheapen money. This latter condition being expressed, however, not as a depreciation in money-value, but as an increase in the price of goods, as, say, one must pay two dollars when before one dollar sufficed. Furthermore it should be borne in mind that the value of money depends, not alone upon its own quantity, but also upon the quantity of the things for which it is to be exchanged, and to ignore either factor is to be equally in error.

That the authorities in Washington hold different opinions from Mr. Tingley on the 'quantity of money' theory is quite evident from their effort to prevent trading with Liberty bonds. Whenever these bonds are used as payment for goods, they become money as truly as though they were so many silver dollars, and the general use of the bonds must tend toward an increase of prices. Mr. Tingley's argument for two blades of grass is, no doubt, sound, as is implied above. He looks with suspicion upon Government control of price. In this he may be correct. History will, no doubt, furnish him

much support. But, on the other hand, monopoly and combination in restraint of trade have become so extensive and powerful that the present-day emergencies may make the policy of price-control imperative. However, it should be realized that any course which does not recognize the influence of the quantity of money is bound to be defective and is likely to defeat its own ends.

CHARLES A. PORTER.

Goldroad, Arizona, May 27.

A Message From the Front

The Editor:

Sir—I am writing this letter to you for two reasons: (1) to discontinue my subscription to your valuable magazine, and (2) to give a few impressions on the War.

(1) My subscription ran out in March. On account of needed economy and the dearth of dollars caused by my sacrificing my professional work in civil life, I am compelled to discontinue the subscription. I have a family to care for. Needless to say, I regret the action necessary.

(2) Your editorials on the War are very encouraging to us over here. It might be interesting to you to receive impressions from one who had already seen eight months service at the front, and one month in the rear. One of my fixed habits in life is to look ahead to provide for emergencies and contingencies. On all work of engineering and mining interest, the future is provided for. Kindly recall that successful engineering is based upon the application of the cold, non-sentimental, non-hysterical, non-optimistic, non-pessimistic facts of science. There is a certain job to be done: six or eight million Germans and Austrians must be killed in order that our wives, mothers, and children may dare to live and call their souls their own. The number of soldiers that the enemy has is far greater than ours and his losses are being made up in part. He must be overpowered and whipped. His armies must be driven out of their trenches and killed. The enemy's country must be entered. Berlin must be captured. The royal family must be executed for gross violations of international law.

To accomplish the above results requires material, men, artillery, aeroplanes, and food. The United States should immediately take steps to equip and maintain an army of ten million men. It is numbers that count, as well as grit and tenacity. One tenacious man may kill 10 or 15 Boches, but 20 Boches may overpower the one.

The British are calling out men of 50 years of age. Should not America bow her head in shame when only a small percentage of her men under 30 have actually been called to the colors? Are we going to wait for Britain's aged men to fight our battles? It would be wasting time to attempt to convince any unconvinced person that America is fighting her own fight. Any person with the slightest grain of common sense knows now, in the year 1918, what Kultur means.

True, the submarine is limiting the amount of tonnage available for shipping material. If not subdued,

it will sink more tonnage, but America is capable not only of replacing sunken tonnage but of providing more than is sunk. The American enjoys tremendously a huge task. The whole nation should take delight in carrying to success a job that staggers the world and yet contributes to life and freedom. We must prepare the United States as though we alone were fighting Germany. Let us refrain from depending on the British navy and the French and British armies. Let our Uncle Sam assume his full responsibility as a man and say, "Johnny Bull, damn the expense, old top; I am going to finish this job. If the Boche by any lying thieving trickery should temporarily get the upper hand on your army and navy, I will drive him back into his hole, if it takes all my men up to 60 years of age and all of my dollars."

In conclusion: (1) There is still a Boche army of probably 10 millions. (2) Pay no attention to starvation and revolutionary stories from Germany. Every since 1870 the infants of Germany have been fed on 'world-empire' milk. Next year Germany will lack nothing in the way of food and material on account of the Russian debacle. (3) The Boche recognizes no authority but force. (4) Let all the energy of the United States be directed toward building ships, an invincible navy, an army of 10 million, universal military service, ammunition, artillery, aeroplanes, food, and all the accompanying paraphernalia of armies and navies. Let the people refuse to purchase any luxuries, clothes, furniture, only the bare necessities of life. Remember we wear our clothes until they rip. We cut down all excess baggage. We carry only our professional tools. Let the people at home do as much as they can do; they still escape the chances of gas, bombs, shells, and machine-gun bullets. (5) Deal summarily with the Boche spy and the pro-Boche. Organize sun-rise firing squads for all the reptiles of that type. (6) Pray to God for success in the greatest crusade against evil that has ever been undertaken.

AN OFFICER AT THE FRONT.

Somewhere in France, April 30.

Mexican Export Taxes on Metals

The Secretary of Hacienda of Mexico has issued the following schedule of taxation upon exports of metals and minerals; the figures given being reduced to American gold per pound: gold, \$21.47½; silver in bars or ingots, 63¾c.; silver in mineral or concentrates, 89¾c.; copper in bars or ingots, 1.19c.; copper in minerals or concentrates, 1.42c.; lead in bars or ingots, 0.00155c.; lead in minerals or concentrates, 0.002139c.; zinc in bars or ingots, 0.005589c.; zinc in minerals or concentrates, 0.007454c.; tin in bars or ingots, 2.585c.; tin in minerals or concentrates, 2.703c.; antimony, in bars or ingots, manganese, 0.001863c. on the contained metal; mercury, 4.784 cents.

FERRO-MANGANESE is quoted at \$250 per ton for 70%, with \$4 per unit for each per cent over 70. For 16 to 18% spiegeleisen the price at the furnace is \$70 per ton.

The Gypsum Industry in 1917

The total quantity of crude gypsum in the United States in 1917 was 2,696,226 short tons, a decrease of 61,504 tons from the output of 1916. This decrease was due to the reduction in building operations in the second half of the year. The total value of crude and calcined gypsum, however, was far greater than ever before, amounting to \$10,502,509. According to R. W. Stone, of the U. S. Geological Survey, gypsum produced and marketed was as follows:

State	Quantity mined, tons	Total value of crude and calcined gypsum
California	30,552	\$ 96,718
Iowa	461,864	1,837,639
Kansas	79,331	424,611
Michigan	375,803	1,549,614
New York	606,268	2,036,820
Ohio	270,538	1,223,301
Oklahoma	158,017	544,129
Texas	237,328	996,262
Wyoming	55,814	197,867
Other States and Alaska	400,681	1,595,548
	2,696,226	\$10,502,509

As might be expected, the average price per ton for gypsum and its products shows a large increase over the price in 1916. The value of land plaster rose from \$2.04 in 1916 to \$2.74 in 1917, of gypsum for retarder in portland cement from \$1.34 to \$1.65, and of all grades of calcined gypsum from \$3.97 to \$5.55 per ton.

RAPID detection of the sulphate ion in insoluble sulphates and the identification of this ion in general is the subject of a paper by G. Deniges, in the Bull. Soc. Chim., No. 23, 1918. The method, based on the formation of yellow crystals of $\text{Hg}_3\text{O}_2\text{SO}_4$ (the so-called 'mineral turpeth') on the surface of the insoluble sulphate, is used for the microchemical identification of the SO_4 ion. As a reagent, dissolve 10 gm. of crystals of $\text{Hg}(\text{NO}_3)_2$ in a mixture of 100 cc. of H_2O and 1 cc. of HNO_3 (sp. gr. 1.39). To detect CaSO_4 treat 0.02 to 0.03 gm. with 2 to 3 cc. of the reagent and mix, obtaining immediately the yellow coloration. The test may be made on a slide using 1 drop of reagent. Hg_2SO_4 responds to the test almost as rapidly as CaSO_4 , giving the same microscopic appearance. With SrSO_4 the transformation is slower, requiring 15 to 20 seconds in the cold, but is instantaneous on warming. BaSO_4 suspended in the reagent does not react in the cold, even after long contact; on heating to boiling a yellowish coloration results that is intensified on prolonged boiling. PbSO_4 is colored immediately in the cold. These sulphates are readily distinguished, even in their mineralogic forms. The precipitated BaSO_4 of commerce contains sufficient soluble ionized SO_4 (H_2SO_4 , alkali sulphates) to give the test directly. To detect the SO_4 ion in complex mixtures, precipitate out BaSO_4 or SrSO_4 in a slightly acid (HNO_3) solution, filter, wash, and apply the test. The test cannot be directly applied in the presence of halogens.

GOLD OUTPUT of the Rand in March was 696,000 oz., compared with 714,000 in January, and 787,000 oz. in March 1917.

THE GRANBY SMELTER AT GRAND FORKS, BRITISH COLUMBIA

Matte-Settlement and Slag-Disposal at Grand Forks

By WALTER B. BISHOP

On leaving the furnaces the slag and matte are received in a series of settlers, preferably five, arranged as shown in Fig. 1. The matte is tapped into ladles that are taken to the converters; the slag is granulated and conveyed in launders, having a fall of one inch to the foot, to a bin where it is dewatered and elevated to slag-piles by belt-conveyors.

MATTE SETTLEMENT. It is possible to collect most of the matte in the first settler, with decreasing amounts in each of the other four. Each furnace has three settlers exclusively, and the slag-flow from two furnaces is combined in the fourth settler as shown, continuing through the fifth settler to the granulating nozzle. This arrangement was made so as to allow a further chance of settlement of entrained matte, in an endeavor to clean the slag. As the flow of slag through the fourth and fifth settlers was doubled, it assured sufficient heat to keep them properly open. This arrangement also effected an economy in the quantity of water used for granulation, as it enabled the slag from two furnaces to be granulated at one point. There is but little loss of heat between the furnaces and the granulating nozzles. It should not amount to more than a loss of 15°C. The slag stream, when it leaves the last settler, drops into an old water-jacketed furnace-spout. This allows the stream of hot slag to be adjusted in reference to the impinging

stream issuing under water pressure from the nozzle, so that the granulation is under control.

The matte that is tapped from the first settler contains about 31% copper. The fourth and fifth settlers are tapped at intervals of several days, and it is of interest that this matte is often of much higher grade than ordinary matte, sometimes carrying as much as 50%. Under the best operating conditions of the blast-furnaces a matte is made that, on arriving in the first settler, allows a product to 'chill out.' In this way the interior of the settler is filled gradually so that at about the end of two weeks, through lack of capacity, it is necessary to remove it. The 'sow' formed consists of a mixture of metallic iron and low-grade matte. For this reason it has been found by experience that a 7-ft. settler is more suited to the needs of this plant than a larger one. It is possible to pick up a filled settler, remove it with a crane, replace with a new one, and leave the furnace operations practically undisturbed. An 18 by 10½-ft. settler has been tried, but for our conditions, experience, both as to cleanness of slag and ease of operation, has been greatly in favor of a series of smaller settlers. Most of the matte is recovered in the first two settlers, while the remaining three give an abundant opportunity for further settlement.

SLAG-LINED SETTLERS. Fig. 4 gives details of a water-

jacketed settler that has proved the best type for the local conditions. It is tapered so as to allow the easy removal of the shell from the chilled 'sow.' This is done by knocking away the clamps and lifting the steel-settler shell by the aid of the crane, away from the chilled content, which is later broken up and sent to the converters. As the slag made is usually very silicious, it is not necessary to line the settlers with highly refractory material. A lining made of the ordinary blast-furnace slag, cast direct from the settlers, has proved to be perfectly suitable for the purpose, but 21 fire-bricks are placed around the tapping jacket. A 2-in. layer of old fire-brick bats is put on the bottom and leveled off with river-sand. Inside the settler is then placed a steel

more, so as to prevent undue strain on the rivets at the top of the settler through expansion in this ring.

The settlers are fitted with welded, water-jacketed, matte-tapping jackets, flanged in two similar halves. These were developed and patented soon after the plant started, by Miles Barrett, the general foreman, and they have given unqualified satisfaction under all kinds of conditions.

WATER USED FOR GRANULATING. Granulating of the slag is done at four places, the slag from two furnaces

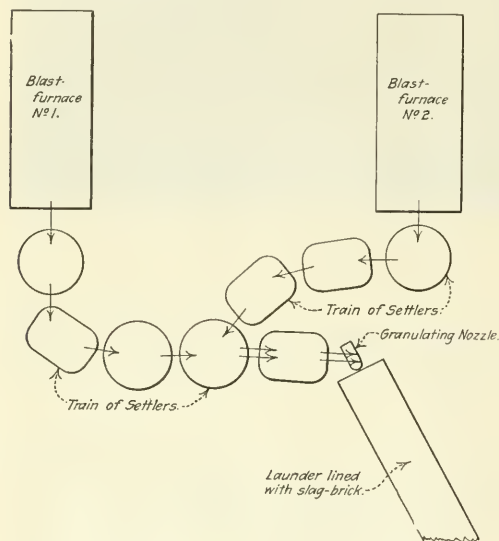

FIG. 1. ARRANGEMENT OF SETTLERS

FIG. 2. LAUNDERS AND BINS

water-jacketed circular form, tapered in the opposite direction to the taper of the settler; this form is about six inches deeper than the settler, and has a 2-in. water-space. The outer sheet is welded, flanged, and free from rivets. Clay at the bottom around the inside serves to prevent slag-leakage, and then a slag-stream is deflected into the space between the water-jacketed form and the settler-shell. This makes a slag-lining, and has done away with the need for using any brick other than that mentioned in the lining of the round settlers. The slag-wall is about 14 in. thick at the bottom and about 7 in. at the top. It has proved thoroughly satisfactory under widely different conditions as to matte-fall and slag-composition, and it gives the steel shell all the protection it requires, besides avoiding the cost of the brick and the masons' work required in laying brick in the ordinary way. In pouring a lining of this kind it is well to keep a good head of water on both the water-jacketed core and the settler itself, and also to bring the slag-lining just up to the 2 by 2-in. welded steel ring and no

being combined at each granulating nozzle. To aid in conveying the granulated slag, the overflow water used in cooling the blast-furnace jackets and the settlers is delivered at the four granulating points. When eight furnaces are in blast there is supplied about 2800 gal. of jacket-water per minute and 1600 gal. of water at 50 lb. pressure per square inch, through four nozzles $\frac{5}{8}$ by 2 in. This is equal to 1400 gal. of overflow water and 800 gal. of pressure-water through the nozzles for each ton of slag granulated.

SLAG BLOCK LAUNDER LINING. Fig. 2 shows diagrammatically the lay-out of the blast-furnaces, launders, and slag-bins. The launders are lined with slag-blocks, which have been found to give more service than any lining material yet tried, including steels of various qualities and hardness. The same size of block is used on the bottom and sides of the launder, the free space being the full width of the block, or 18 in. Such blocks have been employed since 1913; they soon superseded other linings. Some of the blocks have been in steady service for over

two years. Their use has resulted in a marked economy, both as regards the material and the maintenance of the launders. The blocks are cast in molds as shown in Fig. 3; they are 18 by 24 by 3 in., reinforced with a sheet of Trussett metal, 24-gauge, of approximately the same dimensions. We find that a slag of about 43% silica, 16% iron, and 20% lime, if cooled slowly in these molds, gives a satisfactory block. Usually a number of these blocks is cast at one time, and the blocks are then covered with at least a foot of flue-dust. It is well to leave the mold and its contents undisturbed and allow it to cool slowly under the cover of flue-dust for at least six hours. Should angular pieces be required a piece of steel may be placed in the mold and clayed at the bottom so as to prevent slag-leakage. There is but little difficulty in casting angular pieces this way, the Trussett metal being cut to the correct shape.

SLAG-DISPOSAL. The granulated slag and water is received in a bin holding about 250 tons and divided into four compartments. The water is drained off and the slag is discharged through chutes in the bottom of the bin to a belt-conveyor, which runs underneath in the direction of the long axis of the bins.

There are two slag-dumps, called the north and the south. The north dump is the one commonly used, while the one on the south is used only during repairs to the north conveyor, or for reasons of a similar nature. Including the belt under the bin, there are six conveyor-belt sections in the north system and four on the south. The belt under the bin is arranged so as to deliver slag at either end, as required, by a suitable reversing switch at the motor. The belts are 30 in. wide, 7-ply; they have a $\frac{3}{16}$ -in. cover of rubber on the carrying side and $\frac{1}{16}$ -in. on the pulley side. It is aimed to make a section about 310 ft. between centres and to bring the stream of slag to the belt through suitable chutes with as little concussion as possible, so as to avoid undue wear.

The first two sections of the north conveyor system were built on trestles and the slag was discharged over the end until the pile had extended from the ground to the elevation of the end-discharge. From there onward the conveyors were advanced on the slag-pile, which was formed as shown in Fig. 5. The conveyor is carried on a trestle about 8 ft. above the surface of the slag. The last section of the conveyor differs from the permanent sections in that it has an intermediate S-drive, while all the others have head drives. This S-drive can be placed anywhere along the last discharge-section of the conveyor. There are no trippers for discharging the slag, but the stream is delivered over the end of the last belt. The discharge-belt, which is called a telescopic belt, because it extends down and under the preceding belt-section, is built so that the down-hill end, for a distance of 40 or 50 ft., is directly beneath the section immediately preceding it, and the discharge end of the belt is supported on a carriage with a free movement of 20 ft. In this way, as it becomes necessary to advance the discharge end of the belt, the carriage can be jacked forward without disturbing operations, as there is always sufficient unused belt to pull up immediately below the preceding section.

When this spare belt has been used up it is only necessary to drop the rear take-up car farther down-hill, insert a spare piece of belt, and continue as before. When the last belt has been extended to a distance of about 310 ft. a permanent head-drive is installed and a section made, when a new discharge-belt is constructed as explained. In this way No. 4 and No. 5 sections have been formed and No. 6 is now in process. The sections originally had an elevation of about $18\frac{1}{2}^{\circ}$. This elevation could be increased considerably if necessary. Owing to the limitations of the ground available, this angle has had to be varied in different sections. The slag reposes at an angle of about 40° .

SLAG-CONVEYOR. The machinery for conveying slag is standardized as much as possible so as to be interchangeable one section with another. All drives are head-drives with the exception of the last or discharge section, which is an intermediate S-drive, as already mentioned, and also with the exception of No. 1 section underneath the bin; this, when delivering to the south, is a tail-drive, but, as the belt is practically flat, it makes but little difference. Each section is operated by a 75-hp., type C, Westinghouse motor, with the exception of the section underneath the bin, which is equipped with a 30-hp. motor. The head pulleys, of 48-in. diam., are crowned and lagged. It is advisable to have not less than 6 in. diam. of pulley for every ply of belt wherever possible. Carriers are spaced at 5 ft. centres and return-rollers have 10 ft. centres. Side-guide rollers are spaced at 20 ft. centres; they are put there more for precaution than for use, the object being to run the belts at all times so as not to touch the side-guide rollers, thus preventing undue wear at the edges. The return-rollers are made from 6-in. pipe in one piece, with the bearing pressed into the ends of the pipe. They have proved successful. When built of several sections, as formerly done, they formed tracks in the carrying surface of the belt.

Motor-controllers for the north system of belts are all placed in a house at the beginning of the No. 3 section north. This allows one man to control all the operations from a convenient point. Controllers for the south section of belts are placed at the beginning of the No. 2 section south. A light cable attached to a safety-switch runs the entire length of the conveying system, enabling operations to be stopped immediately from any point in case of necessity. Telephones are installed at convenient places.

The power used on the No. 3 section north, when running unloaded, is 16 hp., and when loaded is 64 hp. As the power used in moving the conveyor without load is such a large proportion of that when loaded, it is well to run the conveyor as fully loaded as possible. This also reduces the wear on the surface, because a less amount of material is brought in contact with the wearing surface of the belt. In this way, with eight furnaces in operation, and moving about 2880 tons of slag per 24 hours, all the slag made on an eight-hour shift is handled in about $3\frac{1}{2}$ hours running time. This allows plenty of time for cleaning-up and oiling machinery. All belts, with the exception of the end-discharge belt, are run at the speed

of 500 ft. per minute. The end-discharge belt travels at about 700 ft. per minute. The object of this is to move the old and worn-out sections of belt to the end-discharge. In this way, when these old parts of the belting have been advanced this far, they are thin and usually much narrower than the original 30-in. belt, and have to be driven faster to take care of the load coming upon them. On one section of belt the slag from 2,250,000 tons of ore was carried before it was moved to the last section. On another the slag from 1,800,000 tons of ore was carried before it was sent to the end-section. The slag would amount to 80 or 85% of the above tonnage. The manu-

erly drained in the bin and is loaded correctly, there will be practically no 'slop' or over-running. The carriers are so placed as to allow ready adjustment, which is a great help in maintaining the proper troughing of the belt. There is 3200 ft. of belt in use on the six sections of the north system, and 1900 ft. on the four sections of the south conveyor. The belt under the bin is common to each system.

LABOR FOR EACH EIGHT-HOUR SHIFT. One man is in charge of the bin, and two are in charge of the conveyors. In addition, on the day-shift, one carpenter and two helpers look after the repairs and extensions.

ANOTHER VIEW OF THE GRANBY SMELTER

facturers of rubber belt have shown great interest in the solution of this conveying problem, and the belts have been steadily improved as to durability. It is expected to improve upon the above tonnage in the future.

Various schemes have been tried for brushing the belt so as to free the carrying surface perfectly. None has given such good service as a scraper made from belting, which is given a light pressure against the surface and is placed just back of the head pulley on the under side, provided with an adjustable spring-tension. The strip of belt is held in wooden clamps and is replaced when necessary. Suitable take-ups at the rear ends are supplied for each section. Chutes are built so as to prevent as much as possible the pounding action on the belt produced by the stream of slag when being discharged from one section to another, and they are also arranged so as to lead it with a clear space of 1½ or 2 in. on each side.

The conveyor is supported on a frame-work above the floor of the conveyor building, no decking being interposed between the upper carrying belt and the lower returning belt. Under these conditions, if the slag is prop-

The cost of handling the slag—including power, repairs, maintenance, labor, and extension—is as follows:

	Ore, tons	Cost per ton, cents
12 months ended June 30, 1915.....	617,544	3.8
12 months ended June 30, 1916.....	1,106,115	3.8
12 months ended June 30, 1917.....	685,050	5.6

Nearly all the slag up to 1912 had been poured in a molten condition, being run into pots and hauled by small locomotives to the various dumps. After that time, owing to a shortage of dump-room, the slag was granulated and disposed of as explained above. The design was made under the management of F. M. Sylvester, vice-president and managing director, with the supervision of W. A. Williams, superintendent of smelters. Charles Weckell, the master mechanic, had charge of working out a great many of the mechanical details.

COPPER ORE concentrated in 1916 amounted to 50,935,355 tons, and ore smelted, 6,928,010 tons. The former contained 1.28%, and the latter 4.72% copper.

Iceland Spar in Montana

By CHARLES R. PARSONS

The existence of large deposits of pure calcite has recently been brought to the attention of the Bureau of Mines. These occur near Gray Cliff, Montana, and have been inspected by S. C. Lind, of the Bureau. At the present time there is no considerable market for pure calcite. It is used for the manufacture of some kinds of glass. Perfect crystals of calcite are employed in certain optical instruments. In the past practically all the optical material has been mined from one deposit in Iceland. The crystals from the Montana deposit appear to be the nearest approach to Iceland spar yet uncovered in any part of the world. Since the seventeenth century scientific requirements for optically perfect calcite have been supplied almost wholly from the small deposit on the east coast of Iceland. This consists of a cavity in basalt completely filled with enormous crystals of pure calcite. Rhombohedrons and scalenohedrons, with diameters as great as three feet, have not been uncommon. In recent years, however, the difficulty in securing first-class spar from the Iceland deposit has steadily increased.

While the total amount of spar required is not great, the maintenance of a certain production is necessary for the manufacture of Nicol prisms to be used in dichroscopes for testing pleochroism of gem stones, in polariscopes, in polarizing microscopes, and in saccharimeters. Other substances having as great a difference in the refractive indices of the ordinary and extraordinary rays are all unsuitable for replacing Iceland spar in optical instruments.

It is possible that the Montana veins might be made to yield a commercial product if worked with care. From one of them 600 lb. of crystals are said to have been shipped to Germany, where they sold for \$3000. These crystals had been sorted from about 40 tons of calcite. The Montana deposit lies in two vertical veins in gneiss. The veins are four to seven feet wide, probably at least 100 ft. deep, and are several miles long. The deposits are near the surface, easily mined, and accessible to the railroad. The crystals practically fill the entire vein without any admixture of foreign intrusions. Some crystals have a slight gray cloudiness which renders them unsuitable for optical purposes.

ZINC OXIDE produced by the French process commands 14c. per pound in carload lots and 14½c. in smaller quantities. American process grades are quoted as follows: standard at 10c. in carloads, and 10½c. in less than carload lots; sterling at 9¾ and 10c., respectively; superior 9¼ and 9½c. respectively; and Lehigh 9 and 9¼c. according to quantity.

ALUMINUM SALTS produced in the United States last year amounted to 198,452 short tons, a decrease of 28%. Alum decreased considerably, but aluminum sulphate increased. These sold at \$51.60 and \$32.15 per ton, respectively.

Recent Zinc Patents

Zinc ore, according to U. S. patent 1,255,438, granted to F. Laist, when containing iron, is calcined, leached with H_2SO_4 , the iron is precipitated by the addition of material containing ZnO , for example, calcined zinc ore, and the precipitate, after separation from the solution, is heated in a furnace at a temperature below that of calcination (preferably not over $625^\circ C.$) to render the ferric compounds insoluble without substantial decomposition of the $ZnSO_4$, and the latter is then extracted from this product. Modifications to meet other conditions are covered by addition patents to Mr. Laist and to J. O. Elton. No. 1,255,436 specifies that zinc ore containing arsenic or antimony is leached with an acid solution containing ferric and manganese salts, and the solution is electrolyzed to precipitate the zinc. After electrolysis ferric and manganous salts are introduced into the solution in sufficient proportion to eliminate the arsenic and antimony, and these with any iron are removed by precipitation before further electrolytic treatment. The spent electrolyte may be re-oxidized and used for leaching additional ore. By patent No. 1,255,439 the zinc ore is leached with an acid solvent, the iron precipitated from the solution as a ferric compound, and the resulting solution is treated with finely divided zinc to precipitate such metals as copper and cadmium, which are electro-negative to zinc. The zinc is electro-deposited in spongy form from the solution to effect further purification of the latter, additional zinc is deposited as reguline metal, and the resulting acid solution is re-used for leaching ore. Recovery of other metals is the subject of patent No. 1,255,440, for use when the ore may contain zinc, lead, copper, and precious metals. It is roasted and leached with H_2SO_4 ; the solution obtained is purified, and the zinc is recovered electrolytically. The residue containing the copper, lead, and precious metals and some zinc is smelted, producing a matte containing the copper and precious metals, and a fume consisting largely of oxides of zinc and lead. The zinc is extracted from the fume by dilute H_2SO_4 , leaving a residue high in lead, and the copper and precious metals are recovered from the matte.

Another patent for extracting zinc from ores, No. 1,256,802, has been granted to E. A. Johansson. By this method a charge of zinc ore containing sufficient carbon to unite with the oxygen of the ore to form CO is introduced into an electric resistance-furnace and an electric current is passed through a portion of the charge so that different parts of the charge are heated to different temperatures. The CO_2 formed in the cooler portion of the charge is caused to penetrate successively the hotter parts of the charge so that the remaining unaltered carbon will reduce the CO_2 to CO . This avoids detrimental oxidation of the zinc by CO_2 .

LITHIUM MINERALS (amblygonite, spodumene, and lepidolite) mined in this country in 1917 totaled 2062 tons, valued at \$42,912. California and South Dakota produce these minerals.

The Human Side of Mining Engineering

By JAMES F. KEMP

*In this year of our Lord nineteen hundred and eighteen, you are holding Commencement under conditions different from any previously experienced by the School of Mines. Under those which have hitherto prevailed a scientific theme would be appropriate for this address. There are many such. Geology has so enveloped itself in the very fire of the mining industry that the themes concerned with structure and origin are fundamental. Yet in this period of hot volcanic feeling, when all over the broad land that with solemn pride we call our own, all good men and women are asking but one question, what can we do to serve, it is the human questions which alone seem appropriate for discussion, and it is to the human side of relations between workers, whether they are in the office or in the mine, on the surface in the sunshine and the daylight or underground with the searching ray of the carbide lamp, that I desire to direct your thoughts. You who graduate today just as those who have taken their diplomas at previous commencements, will sooner or later have to meet the problems presented to and by the workers. You observe that I make no distinction among workers. We are all workers.

The old relations which have prevailed among the people engaged at our mines, even if they be of but modest size, have not proved all that our bright fancy might paint. They are not all that could be wished, but as time goes by they will undergo improvement. Many thoughtful observers realize this truth to the full. At the annual dinner of the American Institute of Mining Engineers last February, president-elect Sidney Jennings, in announcing the subject which he planned that the Institute should specifically discuss during his year of office, selected the human side of the industry and the improvement of conditions. It was a striking coincidence, of which Mr. Jennings was not, I believe, at the time aware, that only a few days before in a pamphlet issued to his people, President Shonts of the Interborough Company, which controls in large degree the subways and elevated railroads of New York City, had taken the ground that the human side of their relations must now come up for more serious and continuous attention and for improvement.

These problems are fundamental and the fundamental nature of them comes home to us with exceptional force at a time like the present, when we are all called to rise as one man to the defence of our country. We have prided ourselves on the fact that every citizen in it could truthfully say and feel "it is my country," and could have good reason for the belief that is in him.

Its normal conditions assured him reasonable justice and a fair opportunity to work out his own career. We solve our problems of government with human and necessarily imperfect instruments. Imperfect and partial results are obtained. But the great, important and basal feature of it all, is the conviction deep down in each individual's mind, that he has a free and fair field, and that where wrong exists, as wrong is bound to exist more or less in human life, means are also provided wherewith to right it. If therefore not in war times but in normal times, we can labor to strengthen that fundamental conviction, we prepare for those sudden, almost unbelievable upheavals, veritable earthquakes in human affairs, such as the present one with which German ambitions and unbridled selfishness have confronted us. Our people are responding with such widespread singleness of purpose as to convince us that the course of life in the past in America has prepared a united front in the defence of democracy against its most dangerous, unscrupulous, and insidious foe. President Wilson has gone right to the heart of the matter and his epigrammatic and concise summaries have the convincing force of proverbs, for a proverb, you know, has been acutely defined as the wisdom of the many but the wit of one.

We are to consider for a few moments the ways in which a mining engineer can so conduct the enterprise under his control or in which he shares as to secure the loyalty of all the workers to the company or firm controlling it; and to make them good and loyal citizens.

Mining and metallurgical enterprises in a large proportion of cases differ from other industries. They are often in remote places. The community is built up around the mine or group of mines or around the smelter. The manager must not only employ and pay, but house, feed, and educate. Let me give you one or two illustrations, not necessarily drawn from America. When the International Geological Congress of 1910 was held at Stockholm, in Sweden, an excursion was given the delegates far to the north to the great iron mines at Kirunavaara, situated over a hundred miles north of the polar circle in Swedish Lapland. At Kirunavaara—under the leadership of Dr. Hjalmar Lundbohm, formerly of the Geological Survey of Sweden—there had been developed a huge sheet-shaped mass of magnetite that is very nearly if not quite the largest single body of iron ore yet discovered the world over. A remoter situation could hardly be conceived, nor, in the winter, severer climatic conditions. From a great though somewhat diversified plain there rises to a height of some hundreds of feet the ridge whose backbone for several miles is the great sheet of iron ore, lying with a dip of 70° between other sheets of contrasted eruptive rock. At the foot of the

*Commencement Address delivered at the Missouri School of Mines, at Rolla, on May 24, 1918.

ridge in 1910 a community of 5000 souls had been established. There were 1000 children in the schools, and the school-houses, in which the eight or ten score excursionists were fed, were beautifully constructed and equipped. The houses of the workers were comfortable and convenient, so that to the most superficial observer it was evident that Dr. Lundholm had been moved by an almost pastoral care of his flock.

On the day on which we were conducted along a mile or more of the outcropping ore and while the other members of the party were busy collecting from the ore, the hanging wall, and foot-wall, I sat for a brief space apart by myself and studied over the Arctic expanse of stunted trees, moraines, swamps, and lakes. But continually my thoughts would come back to those 5000 people, men, women, and children, all drawing their support from the mine. There they were, placed right in the hand of the general manager, and his opportunity as well as his responsibility for more than food and clothing were very great. There was a little organized state in miniature, and much more than Swedish *kröner* in dividends was involved in the way their lives were directed.

Let me ask you to turn your eyes next to the West for two more illustrations. The flourishing little city of Anaconda, in Montana, gathers around the Washoe smelter, or as the company now officially calls it, smelter-y. You could not be a half-hour in Anaconda without hearing the name of E. P. Mathewson, until recently the manager of the works, and now moved by the exigencies of the War and his Canadian citizenship to develop a new company for the production of nickel, in the Sudbury district, Ontario. But Anaconda is Mr. Mathewson's masterpiece—and we see not alone a great and thoroughly organized smelting plant, but good homes, good roads, a park, a fish-hatchery, and a hundred other signs of wise and far-sighted management. One also finds a singularly devoted staff of workers, reaching into the thousands and animated by one spirit of loyalty. We understand why the Mining and Metallurgical Society of America awarded its gold medal to him in 1917. Mr. Mathewson passed on to his successor not alone the management of the great works but responsibilities not unlike those of the bishop of a diocese.

Were you to go farther west to the valley of the South Fork of the Coeur d'Alene river, deep down between the mountain ridges of Idaho, you would find the trim little town of Kellogg, adjoining the mines, mill, and smelter of the Bunker Hill & Sullivan company. Homes for the workers with a plot of ground, which can be bought from the company under favorable terms, are the striking features to a visitor. Instead of the slovenly cabins and unattractive boarding-houses so often the rule in Western mining camps, one notes comfortable homes with little gardens in which a miner and his family may take pride. In these as well as in other ways in connection with this mining enterprise, the wisdom of Mr. Stanly A. Easton's far-sighted management become impressed on an observer.

As I have stated, mining and metallurgical communities are relatively isolated as compared with those de-

pendent on other forms of industry to a degree not often the rule in other lines of employment. The miner also works either by himself or in small groups, usually underground, often in confined places, which may be wet, or sultry and hot, and which often involve some personal risk. The air is frequently bad. We cannot wonder if, when he comes to the surface, the miner, more than other workers, craves excitement and change. If a saloon is available, the poor man's club, as it has been wittily called, he resorts naturally and inevitably to it, and in the social companionship of his fellows, seeks in the artificial excitement of stimulants the change for which he not unnaturally longs. If he is in a small and isolated place, there is nothing to do in the evening or other off-shift part of the time, but to sit around the bunk or boarding-house, where rarely is there provision of magazines or illustrated papers; and where a hand at cards furnishes almost the sole recreation. In such instances, and they are legion in the West, he waits till the end of the week or month, and condenses into a few wild hours the accumulated and not unnatural cravings of days or weeks.

Something surely can be done to meet in a proper and unobjectionable way a need that none can deny. Club-houses or club-rooms at once suggest themselves as the natural solution. Prohibition will soon wipe out the open and above-board saloon and reduce almost to the vanishing point the old means of indulgence. The need of some substitute will be more imperative in the near future than it has been in the past. A social centre must be provided. Magazines and illustrated papers are something. Games of cards without money-stakes have no real objections and would be enjoyed by many. A social glass of non-alcoholic drinks will answer for good fellowship as well as does fire-water, if prejudice can once be overcome. A quiet smoke over an open fire in congenial groups in comfortable chairs is no impracticable dream. Something like howling-alleys or billiards suggest themselves at once.

All these, however, must not be provided as a gratuity or donation by the management, for, if so, they would thwart their own good purpose at the outset; but they must be run like any club by the members, all sharing. Expenses must be borne in some reasonable division by participants. The sense of ownership and responsibility must be cultivated, otherwise in the American atmosphere movements of this kind made with the best intentions by the management of companies or the heads of firms have proved flat failures. I recall one beautiful memorial club-house erected by the families of two departed members of a great firm in a somewhat isolated mining town and placed under the charge of a well-meaning and devoted retired clergyman. The reverend gentleman thought it wrong for the men to play cards or smoke in the building and hedged it around with such restrictions that no miner could have been dragged to its door by the police.

A strong and successful movement for the establishment and acceptable management of club-houses and social centres by the Young Men's Christian Association

has been for some years in progress and has been in instances very successful. The club-houses which were placed under its auspices at all the communities of workers along the Panama Canal during its construction were invaluable and a great means of good. Conditions there were similar to those at many great but isolated mines. Bowling-alleys, amusement-rooms, and reading-rooms furnished veritable oases in the desert and were a great source of good. Similar club-houses are not unknown in mining communities. One at Miami, Arizona, has for some years kept open hospitable doors.

These social centres must be managed with care in one respect, since miners are of all religious faiths and none, of all nationalities and often of strong prejudices, and the social worker in general charge must have so broad and comprehensive a human spirit that his love for his fellow-man as men, is not fenced in by limitations of creed. A very useful help in good works around a social centre can be found in the omnipresent fondness of Americans for outdoor or indoor wholesome sport. Teams from neighboring mines, or from different shafts of the same mine, or from surface-men and underground men, or from any other groups who form natural centres, can be recruited and be a fruitful source of proper entertainment. There may not always be level ground for baseball, or 'soccer,' but the narrowest valley is not so narrow as to crowd out quoits; and in a club-house the bowling-alley may furnish a safety-valve for much god-natured rivalry.

You cannot fail to note that I only urge for mining communities what has sprung up naturally and universally as adjuncts to our training and fighting camps of troops, here and abroad—social centres, reading-rooms, athletic fields and sports, inter-regimental, divisional, or other rivalry at base-ball, and other games—all operating for good discipline and making lighter the disagreeable features and monotony of a soldier's, as they would also of a miner's, life.

One feature of our Western mining communities cannot fail to impress one who lives in them. It is a feature less marked in the older and more settled districts of the East and of Lake Superior. It is the wide-spread feeling that the community is a transient one; conditions are temporary; one will be exhausted and everyone will move on elsewhere. The disposition is thus to accumulate a stake and depart to some other place in which to settle down. Where mines, however, are known to have great reserves for years to come, one of the most important efforts of the management might well be to break this feeling and get all concerned to look upon the community as their settled home. Now, the foundation of the State, as we all well know, is the family. Unless we have a vast predominance of reasonably happy and contented families, in which young people grow up under wholesome surroundings, we cut off at the source our supply of good citizens, men and women. Our so-called and significantly called, mining 'camps,' have too little family life and are too little populated by families and too much by hobo miners. A most important phase of the whole subject is for the management of the companies that are large

enough and permanent enough to justify the movement, to give no small part of their attention to establishing comfortable and reasonably attractive homes, which, where possible with a little tract of land, may be acquired by a miner and be felt to be his own. There is no stiffener of backbone or strengthener of character greater than owning a piece of land and in spare times growing supplies for the table from a bit of a garden located upon it. The miner with a home and a family has a stake in the game and becomes a self-respecting citizen. Not every mining locality is adapted to this development. The great Utah Copper Company, brought into successful operation by your distinguished graduate Mr. D. C. Jackling, is placed far up the narrow Bingham canyon, amid physical conditions precluding little homes and gardens. Suitable land in the dry climate of Utah is too far away to admit of transportation to and fro. But at Kellogg, in the Coeur d'Alene, as I have earlier stated, the Bunker Hill & Sullivan company in a broader valley has accomplished impressive results in building and selling homes to the men, at attractive and reasonable terms. No doubt there are other instances, but, in general, where settlements can be feasibly established in reasonably flat and open country, within practicable distance for transportation, to and fro, we must feel that no more important development could be carried on by the management than to give its attention and a part of its resources to the housing of its men under these circumstances. A company could thus assist in carrying out the scriptural injunction of setting the solitary in families. We would reproduce in this way some of the attractive features of the mining towns in Cornwall, the mother of metal mining among English-speaking peoples, and of Wales, to whose miners we so largely owe the early development of our coal-fields.

The Welsh have another suggestion to give us. They are remarkable singers in chorus, a characteristic not only of the Welsh in Wales but of the Americans of Welsh descent in Pennsylvania. In England, in the contests which have been held in former years by choruses from various parts of Great Britain, the Welsh have been almost invincible. The Cousin Jacks are rather notable singers of hymns in the old country, nor has it been altogether unknown in former years, to have groups of good Methodists from among them in the Lake Superior copper mines, start up a hymn as they were lowered in the cage down the deep shafts of this region. Italians are famous as a people of song—and they furnish no negligible part of our miners today. Folk-songs are also characteristic in the villages of many other lands which send us miners. I cannot believe it is an impracticable pipe-dream that some of these latent possibilities of song and choral singing could be developed under the bright skies and amid the impressive mountains of the West. Children at all events, where they are members of a mining community, have great possibilities for choral singing under proper instruction. Last winter in a little town in Florida, we sojourners seeking relief from the rigors of a northern winter and our neighbors who lived there all the year round, were gladdened and raised quite

out of the dead level of life amid the sand-dunes, because a cultivated English woman, of early musical training, brought the children together for some weeks before Christmas and taught them the beautiful Yuletide carols of the old country and of other lands. Had you heard, as I did, the old-time English songs, the Noël of the French, and the Holy Night, the product of a long-vanished time in Central Europe, you would have wrung the teacher's hand as I did, in congratulation over her happy thought. While there are youthful trebles, there must unquestionably be sonorous basses and high-pitched tenors in our larger mining communities awaiting the magic touch of the conductor's wand.

In all organizations of men which hold effectively together we need some sort of reward and some sort of recognition for long and good service. To a certain extent these rewards come now in promotion for those who show qualities of leadership that make them available as shift-bosses or foremen; but only a man here and there is adapted to these positions. The general run of men work on with no possibilities of recognition. I have pondered the question a bit, as to whether some progressive recognition could not be provided by some increase in pay or some keepsake that would commemorate it. I realize that to some, perhaps a serious, extent class-feeling and the disposition sometimes shown by unions to keep all their members on a dead level of compensation would militate against it. And yet the system of rewards for good work appeals to just as deeply ingrained a characteristic of human nature as does discharge or other penalties for poor work. In almost all cases we have the latter, but we seldom hear of the former. Are we not thereby overlooking an important phase of the whole question.

In a recent address to the Montana section of the American Institute of Mining Engineers at Butte, to which in common with many others I listened with deep attention, President Jennings of the Institute emphasized the great importance of getting the workers of all sorts in our mines and smelters to exercise their wills for the good of the organization. He defined the problem as one to secure the wills in the service of the employer. Perhaps in the topics that we have already covered there may be a suggestion or two leading to this end, in so far as all the points made emphasize the importance of supplying conditions of life conducive to reasonable satisfaction and contentment. Mr. Jennings touched on another phase which is one that I have often pondered, as doubtless have others, and that is summed up in the employer's privilege to hire and fire at will. This is a privilege often exercised very harshly by shift-bosses and minor officials, and, as Mr. Jennings pointed out, it starts a man away from his means of support, breaks up his home if he has one, and causes him injury often quite disproportionate to his offence. He may be a poor miner and be not adapted to the work of this particular type, but he may be well enough adapted to some other branch of employment. It is well, therefore, to think seriously whether, if a man is reasonably industrious and otherwise deserving, some kind of work suited to him cannot

be found before his connection is absolutely severed. In other words, can we not introduce the human element into mining engineering? Shift-bosses and minor officials are often greatly impressed with the powers of authority and are sometimes harsh and hasty in its exercise. On the other hand, discipline must be maintained. Perhaps I may commend to you as a subject worthy of a little serious thought whether there is not some way possible of maintaining necessary discipline and yet supplying a tribunal of some sort which will command confidence and which will give a fair hearing to cases involving at least the temporary loss of livelihood. I am inclined to think that the most important part of the Safety First movement is one to which, so far as I know, practically no reference has been made under this watchword, and that is the safety of a deserving man in his job. The one great thing to keep out of his mind is the smarting sense of wrong and injustice. The fierce individualistic conditions of a new country like our own are fast giving way to more settled ones such as prevail in older nationalities. The sense of security in a job is greater in the older communities, and it has its good side even for the more restless and changing side of our own.

Some of our smelting companies, such as the United States Steel and the International Nickel, have sought with good results to make all the workers participants in the returns of profits. Shares of stock in the several companies have been offered the workers on favorable terms and under such conditions that a portion of the monthly wage could be applied for their purchase. A community of interest is thereby established and much has been done to attach to the company's welfare the 'wills' of the men—the securing of which Mr. Jennings described as a step so greatly to be desired. This plan also meets a condition laid down by President Ripley of the Santa Fe railroad at a dinner given in his honor at Chicago on his seventieth birthday. He established as a principle in the management of great enterprises, such as his own, that changes or improvements must be so planned as to be to the common advantage of all concerned. We know well that this applies also in mines and smelters and finds expression in sliding scales of wage based on the market-price of metals. A rise in price that is accompanied by benefits all round leads to satisfaction rather than discontent. A fall in price leads to suffering to all concerned. While, alas, experience shows us that the spiritually beneficial effects of the latter form of suffering are less appreciated by the wage-earners than the stockholders, yet, after all, kinship is established by this touch of nature.

Gentlemen of the Graduating Class, it is an ancient profession and a great work to which in time and as you reach places of responsibility you will be addressing yourselves. If you gain the positions of management, as past experience with graduating classes leads us to think you will, the problems outlined in these last few minutes will come up for solution. Others have found a way. Let me wish you all success in so doing and by way of encouragement I will close with an incident. On May 12, 1907, in the New York botanical garden we celebrated

the 200th anniversary of the birthday of the great Swedish botanist Linnaeus, the Father of Modern Botany, by dedicating in his memory a beautiful bridge over the Bronx river. Not a few distinguished citizens of Sweden were there and some were entertained at lunch by the authorities of the garden, of whose board of scientific directors I had been a member for 15 years. The honor fell to me to serve as escort at the lunch to his Excellency Mr. de Lagerkrantz, the Minister of Sweden to the United States. For fifteen or twenty minutes we did our best to carry on a conversation that would be of mutual interest. Unavoidably the task grew somewhat labored, when a chance remark revealed the fact that in his home Mr. de Lagerkrantz owned and operated iron mines. Like magic the conversational situation changed and the luncheon came to an end before we had either of us said half the things that rose in our minds. One remark of his Excellency I never forgot. He said that when he was leaving his home amid the iron mines to start for America, his men came down to the train to say good bye. With tears in their eyes, they bade him not to tarry long in America, but to return to his own people as soon as he could. The manager or the owner of a mining enterprise sometimes, as you see, has also been the guide, counsellor, and friend of his people.

The really great man, whether in national life or in the responsible places in industry, is the one who understands his people and gives his best endeavor to surround them with such conditions that their reasonable and proper aspirations may find expression. Of all the men of prominence whose lives have come within the ken of people still living, our venerated President Lincoln is the one who best meets these conditions. Whether we come from the South or the North we must look back from the vantage ground of fifty years almost in wonder at the calm poise which always looked into the future for a united country of devoted citizens from whose hearts and minds the hot passions of war would vanish and in whose thoughts more wholesome, more helpful, onward-moving plans would take their place. In the same way, in industry the large-minded and far-seeing manager is one who to be sure does not fail to realize that mining is a business conducted for profit, exposed to competition, subject to strikes, often to unreasonable demands from the ignorant or the unscrupulous, but who does not thereby become blinded to the fact that he has in his employ not merely hands but souls, not merely instruments from which to extract a full amount of work for the current wage but citizens, the foundation of the State. As he interprets and meets their good aspirations, ensures them just rewards, realizes that only a pair of stout hands and a job stand between them and want, that many are ignorant, that many are in a foreign land with small command of its language, with smaller knowledge of its customs, its history, its life, exposed often to petty graft almost impossible to detect and eradicate, he is called upon to exercise scarcely less than the far-sighted patience and the faith which we see in the deep-set sad eyes of our first martyred president.

Copper Production in 1917

The smelter production of primary copper in the United States during 1917 was 1,886,000,000 lb., which, if compared with the production in 1916, 1,928,000,000 lb., shows a decrease of 2.18%. The total value of the output in 1917, at an average price of 27.3c. per pound, is \$514,910,956, against \$474,288,000 in 1916.

In the following table the production is apportioned to the States in which the copper was mined. The figures represent the content of fine copper in the blister produced, and the smelter output of ingot and anode copper from Michigan.

	1914	1915	1916	1917
Alaska	24,985,847	70,695,286	113,823,061	84,759,086
Arizona	382,449,922	432,407,690	694,847,307	719,035,514
California	29,784,173	37,658,444	43,400,870	44,933,846
Colorado	7,316,006	7,272,178	9,536,103	10,554,851

PREVENTING electrolysis of iron in concrete, according to W. A. Del Mar and D. C. Woodbury in the 'Electrical World,' may be accomplished as shown by laboratory tests on iron set in concrete blocks, which demonstrated that the resistance was located at or near the surface of the anode and that the primary cause was the corrosion of the iron. A current of 15 amp. moves 1 cc. of water in four hours through 10 cm. of rust in a U-tube of 7 mm. diam. Reversal of current causes shifting of the water back to the other branch of the U-tube. The rust near the anode becomes dry, and the moisture is driven out except near the cathode surface. Tests with painted iron bars show that when a current is passed through it, a film of paint undergoes a change in resistance. Making a painted-bar cathode in a water bath and observing the formation of water bubbles under the paint-film shows the phenomenon to be due to endosmosis. No blisters are formed when the bar is made the anode.

GOLD OUTPUT of the Rand in April totaled 717,000 oz. For the first four months of the current year the total is 2,786,000 oz., against 3,032,000 oz. in this period of 1917. Floods in February reduced the yield considerably.

COPPER CARBONATE is in active demand at 30c. per pound.

A Small Mechanical Sampler

*Although the device to be described was used in the sampling of carnotite ore, it may be of service in a laboratory or mine-sampling plant. The ore is reduced to pass through a 10-mesh screen placed at an angle of 45°, giving the following product:

Mesh	%	Mesh	%
On 14	2.0	" 65	11.2
" 20	9.4	" 100	5.4
" 28	15.0	" 150	2.0
" 35	34.5	" 200	0.6
" 48	19.0	Through 200	0.9
			100.0

All dust collected passes through a 200-mesh screen.

The ground material was easy to sample. This device was so arranged that one four-hundredth of the entire weight of ore treated was cut and collected as a representative sample. This sample was mixed with an equal

SMALL MIXING AND SAMPLING APPARATUS

proportion of the dust collected, quartered, split, and a final sample taken.

The mechanical sampling apparatus consists of two Snyder samplers with a mixer between. These samplers were cast-iron pans 16 in. diameter with flaring sides, set edgewise on a horizontal revolving shaft. A spout projecting through the flaring side of the pan passed under the feed-spout at each revolution of the machine and cut and delivered a sample.

As shown in the figure, the operation is as follows: Spout *b*, projecting through the flaring side of pan *a*, passes at each revolution under feed-spout *c*, and delivers a sample into the spout *d* of the revolving mixer *f*. During the remainder of the revolution of the pan *a*, the stream of ore from feed-pipe *e* is diverted as reject into spout *c*. The cut sample from the first pan passes through spout *d* into the mixer *f*, and the mixed material discharges therefrom into feed-spout *g*. The stream of

the sample passing from spout *g* is again cut by the projecting spout *b'* of the second pan *a'* at each revolution, the cut sample passing into spout *i*, which is connected with the sample-bin below. The stream of ore during the remaining part of each revolution is diverted by the flaring side of pan *a'*, and is delivered as reject through pipe *h*, into the ore-bin below. Pipes *e* and *h* are connected with the same ore-bin.

The entire sampling machine is enclosed in a dust-proof box made of galvanized iron 28 by 20 in. by 45 in. high. One side of the housing could be removed for inspection of the machine; the other contains a door. The removable side is packed with felt, and the door is fastened to the box by means of hand-screws.

The opening of the spout in the pan is 1½ in. One-twentieth of the entire quantity treated is cut by the first pan, the second pan also cut 1/20 of the sample, the final sample obtained being 1/400 of the total ore passing through the machine.

NEW METHOD OF BURNING POWDERED COAL. Run of mine or slack coal is crushed to 1½ in. or smaller and dumped on a conveyor belt which carries it to magnetic separators to remove tramp iron, and then to a 700-ton steel storage bin. From this the coal is admitted to a 10-ton per hour rotary drier, which reduces the moisture content to about 1%. The dried coal is crushed and pulverized to 95% through 100 mesh and 85% through 200 mesh, the fine dust being carried from the air-separation mills to an 8-ton storage bin, from which it is drawn into two 5-ton blowing-tanks. The operator, on signal, admits compressed air above the coal in the blowing-tanks, and from the floor a valve to a 4-in. transport pipe opens through which the coal is delivered. A weighing dial regulates the amount passed. Each transport pipe starts from a point near the tank bottom and passes out near the top. The coal moves along the transport pipe to bins at the furnaces where required. Controllers are attached to the bottom of the hopper at the furnace-bin to regulate the exact feed to each burner. The burners are cast-iron pipes with specially shaped elbows. The air for combustion enters the elbow under a pressure of 1½ oz., and the compressed air conducting the powdered coal under a pressure of 6 oz. expands down to 1½ oz. and mixes with the combustion air. The control of the coal-feed permits the use of any flame desired, either oxidizing or reducing. The burners are used in 70-ft. slab-furnaces and for billet-heating furnaces. The steel as it comes from the furnace is said to be 'softer' than that treated in natural-gas fired furnaces, and the absence of an excess of air reduces the formation of scale to a minimum. The furnace temperature is regulated by the amount of coal passed to the burner, and by the quantity of air admitted. Air-firing at 1½ oz. reduces the abrasive action on the brickwork of the furnace.—'Iron Age.'

CLAY IMPORTS into the United States last year amounted to 293,678 tons, valued at \$1,647,525. In 1916 the totals were 317,465 tons and \$1,645,850.

*Abstract from Bull. 103, Mineral Technology 11, U. S. Bureau of Mines, 1917.

Splicing Wire Rope

*Wire rope is susceptible of perfect splicing. A smoother and better splice can be made in this than in manila rope.

Splices for running rope are all known as the long splice, and should be put in from 20 to 50 ft., depending upon size of rope and condition of work. The diameter of the rope is not altered, nor the strength of the rope perceptibly weakened. The accompanying sketches explain splicing in all its stages, and by a little study of them and carefully following the directions any ordinary man can make a successful wire-rope splice. The direc-

to make a 30-ft. splice. A small clamp may be used to prevent the lashing from slipping on the ropes where the blocks are hitched. See that the hoes overlap about 30 ft., about 15 ft. each way from the centre. Then mark the centre of both ropes with a piece of chalk, or by tying on a small string. Proceed to splice, with the blocks remaining taut when it is necessary, but a better way is to remove the blocks, throw off the rope from the sheaves, let it hang loose on the shaft, and then proceed with the splices on the ground or floor, or scaffold, as the case may be.

(2) Unlay the strand of both ends of the rope for a distance of 15 ft. each, or to the centre strand of both ends of the rope for a distance of 15 ft. each, or to the

Fig. 1

Fig. 2

Fig. 3

Fig. 5

Fig. 6

tions given are for making a 30-ft. splice. When a longer or shorter splice is required, proportionate figures will apply.

In most cases the rope can be applied endless. Where the endless rope cannot be put on, the rope must be placed around the sheaves, drawn tight with tackle-blocks, and the splices made on the spot as in Fig. 1.

The following tools are required: A hammer and a sharp cold-chisel for cutting off ends of strands, a steel point or marlinspike for opening strands, two pieces of heavy tarred marline or thin rope with sticks (Fig. 5) for untwisting rope, a pocket-knife for cutting the hemp core, and a pair of two-pound copper mallets.

(1) Place the rope around the sheaves and draw it taut with a pair of tackle-blocks (Fig. 1). The blocks should be hitched far enough apart to give room between

centre mark. Cut off the hemp cores close up, as shown in Fig. 2, and bring the bunches of strands together so that the opposite strands will interlock regularly with each other. (Fig. 3).

(3) Unlay any strand A, and follow up with one strand of the other end, laying it tightly in the open groove made by unwinding A; make the twist of the strand agree exactly with the twist of the open groove. Proceed with this until all but 24 in. of one are laid in. Cut off A, leaving an end about 24 in. long.

(4) Unlay strand 4 of the opposite end and follow with strand D, laying it in the open groove as before, and treating this precisely as in the first case (Fig. 2). Do the same with B and 2, stopping 6 ft. short of the first set. Next, with 5 and E, stopping as before, then with C and 3; and lastly with 6 and F. The strands are now all laid in with ends 6 ft. apart, as shown in Fig. 4.

(5) The ends must now be secured without enlarging

the diameter of the rope. Take two rope clamps (Fig. 5), and fasten them to the rope, as shown in Fig. 6; twist them in opposite directions, thus opening the lay of rope.

Next, with a knife cut out the hemp core for the necessary distance. Now straighten the ends and drive the marlinespike under the strands (Fig. 6), and work the end into the space previously occupied by the hemp core; then twist the clamps back, closing up the rope. The ends should be laid in, side by side—that is, they should not be crossed over each other. At the point where a tuck is made, hammer with copper mallets to fix the strands firmly in place. Next, shift the clamps and repeat the operation at the other five places, and the splice is made. In splicing rope that is to run over small sheaves or which is to be subjected to excessive strains, wrap the end of each strand for the distance that is to be tucked into the centre of the rope with tarred marline or electrician's tape, which will increase friction and prevent the ends from working out.

If the rope becomes slack, in time, and runs too loose, a piece can be cut out and the rope tightened up. This will require a piece of rope about 60 ft. long and two splices, one splice to put on the piece of rope, the other splice to join the two ends together.

The patent flattened-strand splice is no more difficult and is equally as effective as in the round-strand cable. The method of making this splice is identical up to the point of tucking in the ends of the strands. A slightly different treatment is required in this operation, due to the ratio in the size between the strands and the hemp core. The strand ends (see paragraph preceding directions) should be from 24 to 60 in. long, according to the diameter of the rope. Straighten out the ends of the strands by eliminating as much of the spiral form as possible. The entire length of each strand end is then wrapped with insulating tape, tarred marline or strips of burlap, until its diameter is slightly in excess of that of the hemp core. The tuck is then made similar to that of the round strand splice.

In styles A and C it is necessary to turn the strand sideways at point where it passes to centre of cable, thereby preventing a bulge in the cable. In cases of ropes having five strands, the odd tuck is made at the centre of the splice.

HYDRATION of the separate constituents of portland cement clinker has recently been subjected to investigation by G. A. Rankin, of the Geophysical Laboratory at Washington. From this study it is seen that the initial set in portland cement is probably due to the hydration of tricalcic aluminate; that the hardness and cohesive strength at first are due to the cementing action of the amorphous material produced by the aluminate and of tricalcic silicate; and that the gradual increase in strength is due to further hydration of these two compounds, together with the hydration of dicalcic silicate. The value of portland cement depends upon the fact that when finely powdered and mixed with water an amor-

phous gelatinous-like material is formed on the individual grains, cementing them together. The amorphous material results from the major constituents, tricalcic silicate, dicalcic silicate, and tricalcic aluminate. Of these constituents, the compound tricalcic silicate, which makes up about 30 to 35% of an average normal portland cement, is the one which hardens and develops the greatest strength within a reasonable time. This is due to the gelatinous hydrated silica which is readily released when this compound, in finely powdered state, is mixed with water. The essential process for the manufacture of portland cement is the formation of this compound. Unfortunately, the increase of the percentage of the tricalcic silicate does not appear economically possible at present. A more feasible plan of attack for improving cements would appear to be to release hydrous silica for some compound such as dicalcic silicate, which contains a higher percentage of silica than tricalcic silicate, by the dissolving action of some suitable electrolyte. Investigation along these lines may result in the discovery of a cement which will enable one to prepare a concrete closely approaching the ideal, that is, grains of sand cemented together with hydrous silicate, the toughest of sandstones.

CONSUMPTION OF CHEMICALS AT THE HOLLINGER MINE. During 1917 the 2500-ton mill treated 508,139 tons of \$8.67 ore and 6162 tons of old concentrate assaying \$7.71 per ton. Extraction was 95.16%, with a consumption as follows:

Material	Pounds per ton
Cyanide	0.448
Lead acetate	0.331
Lime	2.257
Zinc	0.360

The cost of treatment was \$1.017 per ton. Stamp-duty was 15.4 tons per day. Pregnant solution precipitated averaging \$4.038 per ton amounted to 2.15 tons per ton of ore treated.

DIVIDENDS FROM THE BIG FOUR. Annual rate of distribution of these companies is now \$8 by Chino, \$4 by Nevada, \$4 by Ray, and \$14 by Utah, according to the 'Boston News Bureau,' but the outlook is uncertain for the future, on account of increased costs and taxes. The following tabulation shows dividend disbursements by these companies:

	Chino	Nevada	Ray	Utah
1917	\$8,612,802	\$8,297,747	\$6,624,152	\$23,555,105
1916	7,177,335	7,487,963	4,337,935	19,493,880
1915	2,609,860	2,989,185	1,872,319	6,904,083
Three years total	\$18,399,997	\$18,774,895	\$12,834,406	\$49,953,068
Total to date....	27,488,132	35,771,869	15,555,252	75,770,882

INCREASES made in the production of by-product coke are shown by the fact that the output for the week ended March 30, 1918, amounted to 474,610 tons, being at the rate of 24,680,000 tons per year, whereas in 1914 the total by-product coke made in the United States was 11,219,943 tons. The present rate of production exceeds the total of bee-hive coke in 1914.

REVIEW OF MINING

NEW YORK

Iron-Ore Resources of the World Discussed by A. I. M. E.— Silver Used in Photography.

The annual meeting of the New York Section of the A. I. M. E. was held at the Machinery Club on May 23, when several well-known authorities spoke on the iron-ore resources of various parts of the world. H. Foster Bain, assistant-director of the U. S. Bureau of Mines, stated that China's resources had been over-estimated; and that, in one instance at least, other minerals had been mistaken for iron ore. He gave a total of 400,000,000 tons available and suitable for modern furnace reduction, and an additional 300,000,000 tons that might be treated by native methods. The deposits are gradually passing under the control of the Chinese government, which has now seen the advisability of modifying the old law that owners of land are also owners of any minerals that may be found underneath. All the iron-ore deposits are controlled by Chinese or Japanese interests; and in this connection Mr. Bain made some interesting comments anent the expansive policy of the Japanese as a nation. In comparing the two principal Asiatic races, China and Japan, it was pointed out that, formerly, agriculture was of primary importance; but that the growth of Japan has led to a change in the national character of industry. This development must inevitably force agriculture to a position of secondary importance, and is due to the fact that, whereas population is increasing, there is insufficient expanse of territory to maintain agriculture as the principal industry of the State. Japan's policy of expansion is therefore logical. The apparent lack of importance attached by China to her mineral resources is explained by the fact that she is still, and is likely to remain for some time, a country where agriculture is the predominant national industry. The Han-Yeh-Ping Iron & Coal Co. is the chief operator in China. Its mines are at Tayeh.

The iron-ore deposits of the north coast of Cuba were dealt with by C. M. Weld, who gave an estimate of over 3,000,000,000 tons available, a figure that has been checked by precise methods of computation. The iron content has been estimated at 40 to 50%, nickel 0.5 to 1%, chromium 1½%, silica 2 to 6%, phosphorus low, and sulphur negligible. The Behlehem Steel Corporation owns a deposit estimated to contain 1,170,000,000 tons, underneath a surface area of 78,500 acres. The Midvale Steel Co.'s deposits amount to 300,000,000 tons; and the U. S. Steel Corporation's, 210,000,000 tons. The total deposits include a large proportion of soft ore, estimated to contain a billion tons of metallic iron. The water content of the average ore is a noteworthy feature, analysis showing 25% of hydrosopic and 13% of combined water. Nodulizing is necessary in order to reduce subsequent expense, and the product from the sintering-machines can be dressed to 55% iron, and of a character so that 90% will be retained on a 10-mesh screen. This nodulized ore can be placed at Atlanta at a total cost of \$2.50 per ton. The smelting of this product has been highly successful, with a fuel ratio of 1 to 1. The pig-iron produced is especially useful for making satisfactory spiegel, high in combined carbon and low in the graphitic variety. When mixed with other iron it is suitable

for ordinary casting work; and is also largely used in steel-making.

An interesting account of the Scandinavian deposits was given by Waldemar Lindgren. The southern Swedish reserves were stated to be small and insufficient for export. The central Swedish deposits were given as 122,000,000 tons. The Lapland reserves have been estimated to contain 1,150,000,000 metric tons of 58% iron, with 11 to 3% of phosphorus as apatite. All the ores in this region contain apatite. Of the total Swedish production of from 6,000,000 to 7,000,000 tons annually, previous to the War one-third of this went to England and the remainder to Germany. It is probable that practically all the production now goes to the latter. Open-cut operations have been changed during recent times to underground methods on account of the severity of the climate. The northern part of Norway contains three important deposits of magnetite, estimated to contain 100,000,000 tons. Concentrating-plants are to be erected, the high-grade ore will be mined, and the normal low-grade ore obtained by open-cut methods. Other important deposits in Sweden contain 150,000,000 tons with an average iron content, in the form of hematite, of 35%. The mineral is flaky, and experiments are being made to determine the best method of dressing.

The iron-ore resources of Brazil were dealt with by E. C. Harder, who mentioned an estimate of 3,500,000,000 tons. The ore is hard and contains an average of 65% iron, less than 0.2% phosphorus, and a little silica. The deposits are, comparatively speaking, inaccessible; and there is no coal locally available. Bonuses offered by the Brazilian government to encourage the iron industry have not been taken advantage of to any extent. The deposits, for the most part, are in the hands of English and American concerns, with France and Germany interested to a smaller extent.

The resources of southern Europe and northern Africa were described by A. C. Spencer, who prefaced his remarks by the exhibition of charts showing the production and manufacture of iron by the various warring nations. In this connection it was interesting to note that in 1911, Germany's production of iron, a large proportion of which was from imported ore, exceeded the total output of the Allies during the year. Estimates of France's ore-reserves are difficult to obtain, but have been estimated at 3,300,000,000 tons, of which 3,000,000,000 tons is in Lorraine. The available reserves in Spain and Portugal have been estimated at 730,000,000 tons. A large proportion of Spain's output, consisting of about 33,000,000 tons annually, goes to Great Britain, and is used in the Bessemer steel industry. Ore reserves of Austria-Hungary have been estimated at from 200,000,000 to 300,000,000 tons. Greece has 100,000,000 tons of nickeliferous ore, similar to the Cuban deposits; and Mr. Spencer stated that Cuban methods of treatment were being modeled on Grecian practice. Italy's ore reserves are negligible. Algeria and Tunis have from 100,000,000 to 150,000,000 tons of 50% Bessemer grade ore available.

The annual report of the Eastman Kodak Co., in which a net profit of \$14,542,657 for the year is recorded, draws attention to an industry which absorbs a large quantity of silver. The white metal used in the manufacture of plates, films, and papers, is practically unrecoverable; so that con-

sumption from this source must be placed in a different category from that which goes into circulation as coinage, or is made into ornaments or plate. The Kodak company uses between three and four million ounces of silver per year at its works at Rochester, N. Y., together with a small amount of gold and platinum.

DENVER, COLORADO

Re-opening Old Mines.—Oil-Shale and Lignite.

After several years of quiet in Colorado metal-mining conditions are rapidly changing for the better. The improvement seems to rest both in the resumption of activities in old districts and old mines and in new branches of mining, that is, new for this State. Space forbids enumerating the old mines undergoing rehabilitation; they are scattered throughout every mining county. One gets news of interesting work in centres that have been almost forgotten for a decade or more.

The Rawley mine, almost on top of the continental divide, is being equipped with an aerial tram to convey its ore 8 miles to its mill at Shirley. In northern Gilpin county, early production is anticipated from the long-abandoned but once famous Perigo and Gold Dirt mines. These, together with the War Eagle, have been acquired by Kentucky interests, and will be re-opened immediately. Operating as the Perigo Gold Co., the new owners have ordered radical improvements in two mills, including the use of the Ruth flotation process for gold-bearing sulphides. In the future, communication with these mines will be chiefly by way of Rollinsville, a station on the Denver & Salt Lake Railroad, instead of through Black Hawk as in early years.

A famous property at Ouray known as the Mineral Farm (because it appeared to early prospectors as 40 acres of richly-mineralized ground) is again attracting attention. Recent work disclosed another great ore-shoot. This property was located in 1875, and had its own smelter within two years. The country rock is quartzite. Some shoots have been remarkably rich in silver, others in copper.

Although much has been published in the press and in U. S. government bulletins regarding one new basis for mining in Colorado, little is told about the progress being made by the men and companies who are in the oil-shale business. Keen interest is manifested in this industry. Denver is constantly visited by men and women from almost every State looking into the chances of securing desirable oil-shale land, and investigating new processes for its treatment. The demonstration of a commercial-size unit of the Galloupe process brought together representatives of many new or proposed oil-shale companies. The Mt. Blaine Oil Shale Co., composed of shareholders and officials in the Tomboy Gold Mining Co. of Telluride, has purchased two Galloupe units of an estimated daily capacity of 50 tons each, and it was a test of one of these units that was open to the public at the Rex Iron Works. Results gave satisfaction to all concerned. This process not only distills the hydro-carbons generated from the shale but it delivers as many as 23 fractions thereof, besides saving ammonia, all in one operation. W. B. Van Atta is president and Hans A. Hansen is manager for the Mt. Blaine company, whose property is near DeBeque, Colorado. It is not now thought by those interested in this industry that any early legislation at Washington relating to the leasing of mineral lands will apply to oil-shale.

Lignite, occurring abundantly near Denver, disintegrates easily and often takes fire spontaneously when in dumps. Believing it to be to the interest of the country at large, W. J. Galligan, Federal Coal Commissioner for Colorado, requests residents of eastern Colorado not to lay in stocks of the better grades of coal for next winter, but to rely upon lignite that will be mined as required. This same request is being made in western Kansas and Nebraska with the object of reducing to a minimum any possible fuel

famine. The operation of Colorado lignite mines has always been a difficult problem, owing to extremes in market demand with the shifting seasons.

The Denver Fire Clay Co., one of Denver's prominent business institutions for the past 42 years, has been re-organized, ownership reverting to heirs of Mr. Bosworth, the founder. Willis W. Case, retiring president, enters the brokerage business in Denver and is succeeded by Harold O. Bosworth. J. Claire Evans, recently manager of the technical supply department of Mine & Smelter Supply Co., is vice-president of the Fire Clay company and will be active in its administration.

MEDFORD, OREGON

Manganese Possibilities of Jackson County.

The director of the Oregon State Bureau of Mines, H. M. Parks, at the request of the Federal government, has made an examination of the manganese deposits in the Lake Creek district in the east end of Jackson county. His report is favorable. He says: "If this low-grade manganese ore is distributed throughout the entire depth of the tuff, they will soon have demonstrated a very large tonnage of ore. In fact, if this be the case, it can be demonstrated

SOUTH-WESTERN OREGON

within a few weeks that ore sufficient to supply the entire needs of the Government will be available, providing proper equipment is installed of sufficient capacity." The report states that the Manganese Metal Co.'s property is 17 miles south-east of the railroad at Eagle Point, connecting with the Southern Pacific near Medford. It is five miles south-east of Lake Creek, near the confluence of Lost creek with the south fork of Little Butte creek. The ore is a psilomelane and pyrolusite disseminated through a flat bed of volcanic tuff breccia. The thickness of this bed of tuff near where development is under way has not been fully determined, but will probably exceed 100 ft. The bottom of this tuff bed outcrops 400 ft. above Lost creek at an altitude of 2400 ft. All the open-cuts sampled assay from 2.13 to 14.86% Mn. the lowest coming from shallow openings. A 12-ft. vertical channel sample taken from a face of the open-cut, beginning 6 ft. below the surface, contained 14.86% manganese. Development so far indicates that the manganese contents improve materially 8 or 10 ft. below the surface. The volcanic tuff-bed in which the ore is found lies between flows of basalt, the overlying rocks of the hills have been largely removed by erosion. It seems that the ore will be found to be the product of weathering and rock decay of the overlying rocks, and that they were concentrated in these porous tuff-beds, largely, if not en-

tirely by the action of descending surface waters. The Manganese Metal Co. last winter built an experimental mill 150 ft. below a large open-pit on the west side of the hill. It consisted of a gyratory crusher of 550 tons capacity, two sets of rolls, and two Faust jigs. There is also a Faust table which has not been operated owing to lack of proper adjustment. Some details of the plant are not well arranged, and on this account they are operated under difficulties. Under these conditions there was produced recently 200 tons of 50% concentrate, containing 10 to 14% silica.

LEADVILLE, COLORADO

Drainage of Yak Mines.—Twin Lakes-Lackawanna District.

The Yak company is experiencing considerable difficulty in keeping the lower workings in the Cord and White Cap drained. The closing down of the Colonel Sellers over a year ago, and the abandoning of the Moyer by the Iron Silver company, last year, has thrown the entire burden of pumping upon the Yak. The Cord pumps are now handling 1200 gal. per min., and it may be necessary to put in additional equipment. Several new lessees are operating at the Cord with generally good results. The Yak is producing a normal quantity of ore, and with an increase in the price for pyrite will become one of the heaviest shippers of this material.

The Twin Lakes-Lackawanna district is alive with the spring rush of development, which promises to be the beginning of a number of important undertakings. G. W. Buehler of Brooklyn, New York, president of the Miller Gold Mining & Milling Co., has entered the district, and is now engaged in bringing supplies and materials to his property in Lackawanna gulch. Just before last winter caused operations to be suspended, the Miller was the scene of a rich gold discovery, the greatest that has been made in that part since the Mt. Champion mine was found. The vein cut at the Miller is 2 ft. thick, and varies from \$50 to \$150 per ton. Preparations are being made to undertake work on a large scale including opening the vein for several hundred feet in either direction. The property is equipped with modern machinery, has its own power-plant, and a saw-mill. Mrs. Mabel Miller of Twin Lakes has been the active manager of the property for two years.

GOLDEN, BRITISH COLUMBIA

Mining in North-East Kootenay, Embracing the Golden and Windemere Mining Districts.

During the past season (ended early in March) the Paradise mine shipped 2400 tons to Trail. The ore is known as 'sand carbonates,' and is almost self-fluxing. It averaged 50 oz. silver and 50% lead. Total shipments were 185 carloads. Regular shipments will commence at an early date. New development this year will be the continuation of No. 4 adit another 200 ft. at least.

The Sitting Bull Mining Co. did considerable development in 1917 and 1918. A light aerial tramway was erected. The ore is fine-grained galena and will average 46 oz. silver and 45% lead. Openings consist of several adits and shafts. The owners this season intend to construct a wagon-road from the head of Boulder creek to junction of the Horse Thief road, west of Wilmer. They will put in a compressor, etc., and drive a long adit. On completion of road shipments will be made.

The Delos copper claims are being worked by F. W. Wonn, of Seattle, representing Eastern United States capital. Buildings are under construction and development is progressing.

Considerable work was done on the Isaac property in the 1917-18 season. Last year 4 cars were shipped, and in 1918 an equal number was taken out for shipment, but only one hauled to rail at Brisco. Ore is an argentiferous galena.

The Lead Queen has been worked steadily since 1916.

Shipments were made in that year and last, but none this past winter, although some was taken out during development. This and the adjoining group (Steele) have possibilities as silver-lead producers. About 800 ft. of tunneling has been done on the Lead Queen, also surface work, and about 400 ft. on the Steele.

A 20-ton trial shipment was taken out last fall from the Mabel R. Ore carries 8 to 15 oz. silver and 80% lead.

This district has two promising low-grade lead-silver properties in the Giant at Spillimachene, and the Lead Mountain opposite Harrogate. Both are close to rail. It is not unlikely that they will be actively worked this year.

TORONTO, ONTARIO

Labor and Assessment Work.—Kirkland Lake and Boston Creek Notes.

The difficulty of procuring an adequate supply of labor, which has been severely felt by the mining industry of northern Ontario, has been rendered more acute by a recent amendment to the Military Service regulations, rendering aliens liable to be drafted. This will have the effect of considerably reducing many of the mining staffs, especially at Porcupine, where the proportion of aliens employed is larger than in most of the other districts. Porcupine is at a disadvantage as regards labor when compared with Cobalt and Kirkland Lake. At Cobalt, wages have been repeatedly raised automatically, being based on the price of silver, while at Kirkland Lake, companies are better able to pay higher wages than those at Porcupine, owing to the higher grade of ore. There will probably be a further curtailment of gold production at Porcupine, with a closing down of some of the smaller and low-grade mines. The Vipond-North Thompson and Schumacher mines are preparing to suspend work, being unable to compete with the larger mines in the labor market.

A recent order of the Ontario Department of Mines to the effect that claimholders who took advantage of the permission granted last year to postpone their assessment work until this year must make up their arrears, in addition to doing this year's work, created much dissatisfaction among mining men. It was urged that to compel them to do two years' work in one season would entail great hardship and loss. The Hon. G. H. Ferguson, Minister of Mines, after a personal visit of the mining districts, has modified his decision. While no general postponement of work will be granted, it is provided that in cases where two seasons' work is due, only one installment need be performed this year, the second being held over for a year. This will ensure development of claims without the imposition of too heavy a burden at a time when there are great difficulties in securing labor.

Kirkland Lake.—The Lake Shore is now the third largest gold producer in Canada. Starting at full capacity on March 8, the mill during March and April treated 2570 tons of ore; yielding bullion worth \$66,696. The mill ran 97.21% of the possible time. The ore during April averaged \$27.70 per ton.

At the Kirkland Lake mine the work of erecting the mill has begun. It will be the largest plant here, with a capacity of 150 tons daily. Ore reserves are valued at \$750,000.

Boston Creek.—The new 50-ton mill of the Patricia is ready for operation. The property has been developed to the 200-ft. level.

At the Miller Independence a new shaft has been started and is down on a vein showing gold across a width of 12 ft., quartz stringers in basalt.

The new 200-ton flotation plant for dressing old sand and slime has been started at the McKinley-Darragh.

A small quantity of 1000-oz. ore has been shipped from the old Keeley mine at South Lorrain. Preparations are being made to commence extensive mining operations.

ALASKA

Anchorage.—Railroad construction is practically assured for the coming season, as the sub-committee of the House Appropriations Committee at Washington has recommended additional funds.

ARIZONA

Ajo.—The Bullion Bar Mining & Development Co., in the Gunsight district, 24 miles east of Ajo, has developed a promising gold vein, and is to erect a 10-stamp mill.

Bisbee.—Copper production of this State in May amounted to 76,711,507 lb. The largest contributors were

To prospect the mineralized zone exposed by drilling in the Jerome Verde, a drift has been started, to be 420 ft. long.

Calumet & Jerome is to be prospected by diamond-drilling. A contract will be let for 5000 ft. of holes from the 600-ft. level, into the pyritic schist-zone.

Green Monster, Gadsden, Pittsburgh-Jerome, Jerome Superior, Shea Copper, Grand Island, Hayden Development, Dundee-Arizona, Verde Squaw, and Squaw Peak are all actively searching for ore.

Superior.—Water in the workings of the Silver King is now below the 400-ft. level. A shipment of high-grade ore was made to the smelter last week, and it is believed that shipping will continue at the rate of two cars per month.

Grand Pacific is hauling ore for shipment; a considerable quantity having accumulated. A raise has been completed, and a tram is now being constructed from the third level to the ore-bins. The 1900-ft. adit is to be continued another 200 ft., and another 700-ft. diamond-drill hole put down.

Wickenburg.—The Abe Lincoln Copper Co., in Black Rock district, recently installed a 60-hp. Western gasoline engine and hoist, and a 60-hp. Chicago Pneumatic compressor using three jackhammer drills. Development on 5-ft. vein is to the extent of a 1000-ft. tunnel and 400-ft. shaft. Ore carries 10 oz. silver and 11% copper. Charles E. Nathorst, late assistant superintendent of the United Verde, is manager.

ARKANSAS

Fort Smith.—The Fort Smith Spelter Co., which suspended smelting recently owing to an accumulation of slab zinc, has resumed operations.

CALIFORNIA

Grass Valley.—Between its mill and Pennsylvania mine, about a mile apart, the Empire company is constructing an electric tramline, so as to be able to treat all ore at its 60-stamp mill. Work at 2800 ft. in the Empire mine has exposed a good deal of ore.

Brunswick Consolidated is working at reduced capacity on account of unsatisfactory conditions.

Ingot.—The Afterthought Copper Co.'s mine, roasting and oil-flotation plant were closed and 100 men laid off on June 3. The reasons given by the management are that the Government's increase of freight rates by 25%, effective June 10, makes it impossible to ship profitably the heavy concentrates to zinc smelter in Oklahoma and copper smelter at Tacoma. The output of the mine was heavier last month than ever before under the company's management, and the ore was higher in copper. It is reported, but not officially, that the company will erect an electrolytic plant.

San Francisco.—The State Mining Bureau has just completed compilation of the quantities of oil and gas produced during 1917. The figures are based on sworn statements from all producers. The output was 94,433,547 bbl., an increase of 7,370,352 bbl. The official figures are less than the total published by private corporations. The latter, however, make no allowance for water and other impurities in the oil when first produced and gauged. Aside from this difference, it is worthy of note that the Standard

MAP SHOWING COPPER DISTRICTS OF ARIZONA

Phelps-Dodge with 17,749,000 lb.; Inspiration, 10,650,000 lb.; Ray Con., 8,100,000 lb.; United Verde, 6,575,000 lb.; Miami, 5,100,000 lb.; Calumet & Arizona, 4,800,000 lb.; Arizona Copper, 4,130,000 lb.; United Verde Extension, 4,100,000 lb.; New Cornelia, 3,900,000 lb.; and Consolidated Arizona, 2,000,000 pounds.

Calumet & Arizona paid \$2 per share on June 14, making \$4 for the current year.

Clifton.—The U. S. Bureau of Mines rescue-car that had been here for two weeks has gone to Kingman. Examinations of large classes were held at Clifton, Morenci, and Metcalf, 59 passing at Clifton.

Jerome.—Fire on June 6 destroyed property valued at \$200,000 in part of the town of Jerome.

The Verde Combination shaft is down 1000 ft. in schist carrying iron pyrite and chalcopyrite. Another 100 ft. will be sunk.

Oil Co. and the Independent Oil Producers' Agency have regularly supplied the public with accurate information. There were no additions of importance during 1917 to the proved oil-land area as determined by the State Mining Bureau for assessment of 1916. The new Montebello field production was the outstanding feature of the year. The increase in production, for which figures are given above, was brought about by marked drilling activity throughout the State. There was an increase in production in every petroleum-producing county. Los Angeles county showed the highest increase, namely 52% over last year's production. There were 984 wells reported to the State Mining Bureau, for drilling, during 1917. The rate of assessment, levied to support the work of supervision of drilling operations, so as to protect the field from damage by water, is based on the quantities of oil and gas produced and of proved oil land. The rate for the coming year amounts to \$0.146 per acre of proved oil land and \$0.00119 per barrel of oil or per 10,000 cu. ft. of gas. The total amount to be collected is \$130,000.

The figures in detail are as follows:

County	Acres	Oil, bbl.	Gas, cu. ft.	Wells
Fresno	12,993	16,146,797	59,189,000	1131
Kern	56,947	52,688,711	1,927,506,000	4716
Los Angeles	2,401	4,357,162	24,175,000	748
Orange	3,418	14,568,930	655,027,000	467
Ventura	1,726	989,726		355
Santa Barbara	9,023	5,589,223	60,157,000	385
San Louis Obispo	772	74,143		18
Santa Clara	80	18,855		14
Total	87,360	94,433,547	2,726,054,000	7834

COLORADO

Boulder.—Boston capital is said to have secured large holdings of tungsten claims at Nederland.

The Tungsten Products Co. is reported to have acquired the old Strabanan tungsten mine between Victor and Dry Lake.

The Colorado Metal Mining Association has formed an oil section to aid oil development in Boulder county.

Cripple Creek.—Cresson Consolidated paid 10c. per share, equal to \$122,000, on June 10. This makes \$6,295,163 to date.

Georgetown.—The Colorado Pay Rock Silver Mines Co. has been organized to operate the Pay Rock silver property in this district. The total production of the Pay Rock mine is estimated to have been \$2,000,000. The mine is entirely above water-level, and has been worked from a series of tunnels, the highest being 1400 ft. higher than the lowest, which is known as the Ashby. The mouth of this is within the townsite of Silver Plume, and possibly 150 ft. above the level of Clear creek. This tunnel intersects the Pay Rock lode 1945 ft. from its portal.

Green Mountain.—Since electric power is again available, mines here have resumed normal work.—The Pride of the West Mining Co. has shipped five cars of rich lead ore during the past two weeks.—The Dives-Shenandoah, operated by the Dives Leasing Co. has commenced shipments of high-grade silver ore, about six cars having been dispatched during the past two weeks. These shipments by the largest producers signal the opening of the season for Green Mountain.

Nederland.—Mining men of this district have organized to co-operate with the Colorado Metal Mining Association.

Rico.—A strike prevails here, where the men have made demands for the same scale that is paid at Telluride. Production of ore is almost at a standstill, but indications are that the higher wage will be established. During the period from May 7 to 20, twenty cars of copper sulphide ore were shipped by the Rico Argentine.

Romley.—The report of G. E. Collins, general manager for the Mary Murphy Gold Mining Co., operating in the Chalk Creek district of Chaffee county, gives the following concerning operations in 1917:

The net operating loss was \$73,943, plus \$20,104 interest and depreciation, and \$13,956 expenditure on the Red Mountain mines, a total loss of \$108,002. Current assets amount to \$229,961, and liabilities \$120,200. Reserves total \$128,583. Development at the Mary Murphy mine was extremely disappointing. Labor was markedly short. Mining costs increased 58%. In the Red Mountain district, 10,700 ft. elevation, between Ouray and Silverton, the Yankee Girl, Genesee-Vanderbilt, and Robinson mines were acquired from J. M. Hyde, payment to equal his outlay on them. These are old silver producers, opened below 1000 ft. Ore occurs in vertical chimneys, but the areas prospected are a small portion of the whole. Some shoots carry copper, others lead and zinc, both with silver and gold; while others carry all of these metals in a complex mixture. A good deal of low-grade ore is exposed, and chances in the Yankee Girl and Robinson for finding rich ore are good. At the Genesee a 50-ton mill is being built. Complex ore may be sent to the mill at Romley. These mines are wet, and the water acid and corrosive, but new tunnels have reduced this trouble. The Mary Murphy mill dressed 36,231 tons of ore, against 54,954 tons in 1916. The flotation department gave poor results. The pneumatic type of cell has been found the best. Concentrates shipped were 950 tons of iron, 756 tons of iron-copper, and 1754 tons of zinc, valued at \$216,578. Tributaries mined 1040 tons of ore worth about \$25 per ton. Costs were \$4.86 for mining, 18c. for aerial trams, \$2.46 for milling, and 49c. for general, a total of \$7.99. In 1916 this was \$6.79; in 1915, \$5.56; and in 1914, \$5.38 per ton.

Telluride.—During April 113 cars of ore was shipped from Telluride, against 162 in March. The drop is due to curtailment of heavy shipments from the Liberty Bell, which is changing its milling system.

The Tomboy has continued normal shipments of iron concentrate. A fire, caused by an upset carbide lamp, destroyed the change-room at the Tomboy, entailing a loss of \$5000, as the building was not covered by insurance.

The Caruthers lease mill is still closed on account of lack of power. A large amount of ore has been mined.

The roads to the various mines are opening much earlier than in former years. During the past season all-year traffic was possible to the Belmont-Wagner holdings for the first time in many years.

IDAHO

Mullan.—Consolidated Interstate-Callahan reports as follows for the first quarter of 1917:

Ore milled (21.02% Zn, 6.77% Pb, 2.27 oz. Ag), tons	35,881
Ore shipped (48.70% Zn), tons	1,457
Ore shipped (11.65% Zn, 43.19% Pb), tons	725
Concentrate shipped (44.48% Zn), tons	12,591
Concentrate shipped (16.27% Zn, 49.94% Pb), tons	1,579
Zinc contents, pounds	12,621,704
Lead contents, pounds	2,203,660
Zinc recovery, per cent.	79.78
Cost of mining, per ton	\$4.723
Cost of milling, per ton	1.982
Net value of shipments at destination	\$461,744
Net profit, plus and minus miscellaneous amounts	138,087
Dividend	none

Costs show a decrease of 59.6c. per ton when compared with the previous period. On No. 8 level 360 ft. of driving was done in ore assaying 24% zinc and 8% lead. The shaft was sunk to No. 9 level, 200 ft. below No. 8. Ore is

being opened at the new level. The tailing dump of 250,000 tons carries 12% zinc, and is being dressed by flotation. A profit of \$1,000,000 is expected from this reserve, calculating spelter at 7c. per pound.

Consolidated Interstate-Callahan will pay 50c. per share on June 15. This is equal to \$232,495, making \$6,742,355 in three years.

MICHIGAN

Houghton.—It is possible that six or eight of the smaller mines in the Copper Country may be forced to suspend operations, being unable to work profitably with the present price of copper.

Isle Royale has five stamps crushing continuously, and a daily output of 4000 tons of ore is expected soon.

Pinex.—Although White Pine Extension, in Ontonagon county, has done sufficient work to warrant large scale operations, it has been found advisable to suspend until labor and financial conditions warrant resumption.

Recent dividends declared are as under:

Company	Amount per share	Date	Total for 1918
Ahmeek	\$2.00	June 28	\$6.00
Isle Royale	0.50	"	1.50
Oscuela	2.00	"	6.00
Quincy	2.00	"	4.50

MISSOURI

Galena.—A market has been found for the pyrite mined in this district. The mineral is extracted from some old mines where it made mining for zinc impossible in the past. The ore carries 48% sulphur, and the Grasselli Chemical Co. is paying \$26½c. per unit of a long ton, with penalties for zinc.

Joplin.—Production of the region last week was 5578 tons of blende, 48 tons of calamine, and 1259 tons of lead, averaging \$49, \$33, and \$84 per ton, respectively. The total value was \$381,876, making \$10,319,752 for 22 weeks. Missouri contributed \$68,669.

NEVADA

Goldfield.—The Goldfield Consolidated has arranged to treat ore for the Manhattan Consolidated of Manhattan; Red Hill Florence of Goldfield; Tonopah Divide of Gold Mountain district, and other outside properties. Part of the plant will continue to treat oxidized ore from the upper levels of the Consolidated. On account of difficulty in marketing flotation concentrates flotation has been considerably curtailed.

Nelson.—Spring has brought new life to the El Dorado district. Since the Techatticup company decided to do custom milling several small operators have started.

The Wall Street mine, a famous producer of the 'eighties, has been leased to J. C. Gilbert, who is working on the dump containing about 5000 tons of medium-grade ore.

The Crown Queen is also being worked by a night shift under Techatticup superintendence, and the ore sent to this company's mill.

The Colorado-Nevada mill is being overhauled. Work in the mine will be started shortly after.

The Rand mine is to use flotation, the first operator in the district to try it. A K. & K. machine will be installed, and the old tailing dump from the stamp-mill is to be treated.

The Germain lease on the Lombard claim is busy getting its new mill equipment into order.

Allured and Allured, at the Carnation, have discovered a promising vein running parallel to their present workings. More men are to be employed.

The M. & D. Mining Co., after cutting 26 ft. of copper ore in Copper canyon with an Okell core-drill, is sinking a vertical shaft to open it. The company is under Japanese

management, and as this is the only copper prospect in the district operations are watched with interest.

Tonopah.—Production of the district last week totaled \$174,743 in 10,279 tons of ore. Eight mines contributed.

In the apex suit between Jim Butler and West End, the U. S. Supreme Court at Washington on June 10 denied the claim brought by the Jim Butler to recover the value of ore extracted from beneath the surface of their claims by the West End. In bringing the suit the Jim Butler denied an apex existed, but contended the vein was in the form of a roll. The lower courts, in part, sustained this contention, but ruled that the crest of this roll constituted an apex, and that the West End had the right to operate the vein indefinitely in opposite directions on both sides of that point. While this suit was pending, silver and gold extracted from ore mined in the disputed ground was held in escrow, and amounts to nearly \$400,000. This will be retained by the West End. Owing to an incorrect version of the decision being current in San Francisco, shares in these two companies fluctuated violently.

UTAH

The four smelters in this State—at Garfield, Midvale, Murray, and Tooele—are said to be treating normal quantities of ore and concentrate from this State and others in the West. The daily total is between 7000 and 8000 tons.

Alta.—The road to Alta is in good condition for hauling ore to rail. Several mines have considerable quantities ready, especially the Cardiff, South Hecla, and Extension.

Bingham.—Fire broke out again in the Utah-Apex mine on May 27, between the 1300 and 1400-ft. levels. It may be necessary to flood the mine again, as described on page 801 of the 'Press' of June 8.

Park City.—The Silver King Consolidated tunnel is in harder shale, and indications are that the limestone contact is near. The heading is in 6750 ft., advance being 15 ft. daily. The objective is 7000 ft. farther.

Watson.—The Crane Oil Shale Co. is to erect a 500-ton

MAP SHOWING OIL-SHALE AREAS OF COLORADO, UTAH, AND WYOMING.
(From 'Met. & Chem. Eng.')

distilling plant near here. The shale is said to contain 75 to 85 gal. of oil per ton, 24 lb. of ammonium sulphate, and 31 lb. of paraffine wax. A. G. Crane has devised a process of recovery.

The Pioneer Oil Shale Co. is to erect a 200-ton distilling plant, using the process of L. B. Glafcke.

The Ute Oil Co. is to erect a 400-ton shale distillation plant near here. It will consist of 18 retorts. A 95% extraction of oil can be made in 55 minutes, according to recent tests. D. H. Gustavson is consulting engineer.

NEW MEXICO

Mogollon.—The new 250-ton mill of Socorro M. & M. Co. is nearing completion. At the mine ore breaking and development is under way.

The Mogollon Mines Co. treated nearly 5000 tons in May. Improvements are being made at the mill.

Sinking has been resumed at the Central shaft of the Oaks Co. This will be put down to No. 4 level.

Silver City.—A bismuth deposit, assaying 3% metal, is reported as being opened in the southern part of Grant county by I. J. Stauber.

OKLAHOMA

Commerce.—The Triangle Mines Co.'s new 300-ton mill is ready. It contains oil engines, gyratory crushers, rolls, Isbell vanners, etc.

Picher.—The Oklahoma fields last week produced 4538 tons of blende and 971 tons of lead, valued at \$313,207.

WASHINGTON

Northport.—Electric Point Mining Co. paid 3c. per share, equal to \$23,790, on May 25. This makes a total of \$190,320. The mine is in good condition down to the bottom, 800-ft. depth, and is producing a carload of ore daily. Construction of the Riblet aerial tram—2½ miles long—is proceeding steadily.

CONSERVATION OF TECHNICAL MEN

It having become evident that the country is recklessly sacrificing its available supply of engineers, chemists, physicists, and other vitally needed technical men, and the fact being that the existing regulations are ineffective for conserving these men for rendering the duty which they alone do, the Engineering Council, created to provide means for united action and to speak authoritatively for its technical societies has passed the following resolutions:

"WHEREAS, technically trained engineers are indispensable to the Army, the Navy, and the War Industries, in engineering corps, ordnance bureaus and signal corps, in aviation, submarine and tank service, in shipbuilding, and in many other assignments;

WHEREAS, through draft and otherwise many of these irreplaceable men have been and are being diverted, so that their special qualifications are not being utilized, be it

RESOLVED, that in the opinion of the Engineering Council technically trained men of all ages should be enrolled and conserved for technical duties, and special efforts should be made immediately by the War and Navy Departments to find and record such men among drafted and enlisted forces, and to assign them to places in which their special qualifications are needed; and be it further

RESOLVED, that the Engineering Council offers to assist the War and Navy Departments in locating and classifying such men, if its assistance be desired, provided these departments will give the necessary facilities for collecting information about engineers now in the Army and Navy, or whose names are upon the selective draft lists.

These resolutions are offered solely in a patriotic spirit of helpfulness."

ALFRED D. FLINN, Secretary.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

W. J. Loring is in New York.

W. Tovote is at Venice, California.

E. H. Wedekind is in San Francisco.

R. Gilman Brown has been elected a vice-president of the Institution of Mining & Metallurgy, London.

F. W. Bradley is at Kellogg, Idaho, making a visit of inspection to the Bunker Hill mine and smelter.

George E. Collins came to San Francisco from Denver to attend the funeral of his brother, Edgar A. Collins.

E. S. Bardwell is to be in charge of the new ferro-manganese plant of the Anaconda Copper Mining Company.

J. W. Sherwin, of the West End Consolidated at Tonopah, is here.

H. H. Nicholson is examining cobalt deposits in eastern Oregon.

T. J. Anderson is returning to New York from La Grange, California.

Ben. B. Lawrence passed through San Francisco on his way from New York to Oregon.

Robert S. Lewis, Professor of Mining in the University of Utah, is at Huntington Lake, California.

George Purcell Costigan Jr. will deliver a course of lectures on mining law at Stanford University this summer.

L. G. E. Bignell has been appointed sales-manager to Sutton, Steele & Steele, concentrating engineers at Dallas, Texas.

W. H. Freedland has returned to San Rafael, California, from a visit of inspection to the Ducktown Copper Co. in Tennessee.

William Sampson, formerly at the Nickel Plate mine, at Hedley, B. C., is now with the Sunset Copper Co. at Index, Washington.

C. A. Duntley, son of W. O. Duntley, of the Duntley-Cotton Mines Co., operating in Calaveras county, California, is Lieutenant in the National Army.

J. W. Hutchinson, general manager of the Goldfield Consolidated and Aurora companies, has resigned and has gone to Washington to enter the Engineer Corps of the Army.

John C. Ralston, of Spokane, shared the \$1000 prize offered by the National Security League for the best suggestion of a method to get American war aims before the people of Germany.

Milton E. Finney, an early-day mine-operator in Colorado, and owner of the first stamp-mill erected in the Black Hills of South Dakota, died at Oakland, California, on June 2, at the age of 82 years.

The trustees of the United Engineering Society at New York have elected the following to the Engineering Foundation Board: Calvert Townley, Silas H. Woodard, Joseph W. Richards, David S. Jacobs, and H. Hobart Porter.

Alfred Stansfield, Canada's foremost authority on electro-metallurgy, has accepted a commission from the British Columbian government to make a full investigation into the commercial possibilities of electric-smelting methods in the development of the iron-ore resources of the Province. Mr. Stansfield is professor of metallurgy in McGill University.

The Australian Chemical Institute has been formed, starting with a membership of 390 in all States.

The American Mining Congress has organized a chapter in Oklahoma, with headquarters at Oklahoma City.

THE METAL MARKET

METAL PRICES

San Francisco, June 11

Aluminum-dust, large and small lots, cents per lb.	65-70
Chromite, 35% and over, California, per unit	15
Antimony (wholesale), cents per pound, in small quantities	23 1/2

Lead, pig, cents per pound	7 1/2-8 1/2
Platinum, Government price, per ounce	\$105
Quicksilver, per flask of 75 lb.	\$110
Spelter, cents per pound	9 1/4
Zinc-dust, cents per pound	17 1/2

ORE PRICES

June 11

Antimony, 45% metal, f.o.b. California, per unit	\$1.10
Chromite, 35% and over, California, per unit	\$1.25-\$1.50
Magnetite, crude, California, per ton (nominal price)	\$7.00-\$8.00
Manganese, domestic, 35 to 54%, f.o.b. South Chicago, per unit (Government price, effective May 20)	\$0.86-\$1.30
Manganese, domestic, 35 to 54%, f.o.b. east of South Chicago, per unit (Government price, effective May 20)	\$1.01-\$1.45
(Manganese, domestic, penalty of 50c. to \$1 per ton for 8% and up to 25% silica, and bonus of 50c. to \$1 for less than 8 and 5%)	
Molybdenite, per lb., 90% MoS ₃	\$1.25
Pyrite, domestic, New York, cents per unit of sulphur	28
Tungsten, 60% WO ₃ , California, per unit	\$24

For further details of manganese see the notes under that title on this page.

EASTERN METAL MARKET

(By wire from New York)

June 11.—Copper is unchanged. Lead is active and higher. Spelter is steady and stronger.

SILVER

Below are given official (not Government) quotations, in cents per ounce of silver 999 fine. In order to make prompt settlements with smelters and brokers, producers allow a discount from the Government price of \$1, hence the lower price. The Government has not fixed the general market price at \$1, but will pay this price (as from April 23, 1918) for all silver purchased by it. The equivalent of dollar silver (1000 fine) in British currency is 66.65 pence per ounce (925 fine) calculated at the current rate of exchange.

COPPER

On September 21, 1917, the Government fixed copper prices at 23.50c. per lb. for large lots, and 24.67 1/2c. for small lots, effective until June 1, 1918. On this date the prices were re-fixed until August 15, 1918. Quotations in cents per pound are as under:

June	27.47	32.57	

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound. On May 25, 1918, the Government fixed prices until September for grade A spelter at 12c. per lb. for itself and the open market. Lower grades can make their own prices as usual. Sheet-zinc is fixed at 15c., and plate at 14c. per pound.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. The Government is taking 40% of the United States quicksilver output, paying therefor \$105 per flask. Outside of this business the competitive market can make any price as may be desired. Prices, in dollars per flask of 75 pounds:

Date	1916	1917	1918

May	49.10	63.21	100.01
June	42.07	61.93	

Chinese tin is quoted at 84c. on the Pacific Coast.

MANGANESE

A schedule of prices for domestic ore has been arranged by the American Iron and Steel Institute, and approved by the War Industries Board, effective indefinitely after May 28. Prices are per unit of metallic manganese per long ton (2240 lb.), for ore mined and shipped from all points west of South Chicago, Illinois. The prices are on basis of delivery, f.o.b. cars South Chicago. When shipped to other destinations than Chicago, freight rate per gross ton from shipping point to South Chicago is to be deducted to give the price f.o.b. shipping point. For ore shipped from points east of Chicago, 15c. per unit is to be added to the schedule given below. Chemical ores are not included. Prices are based on ore dried at 121 F.

Mn. %	Per unit	Mn. %	Per unit
35 to 35.99	\$0.86	45 to 45.99	\$1.12
36 to 36.99	0.90	46 to 46.99	1.14
37 to 37.99	0.94	47 to 47.99	1.16
38 to 38.99	0.98	48 to 48.99	1.18
39 to 39.99	1.00	49 to 49.99	1.20
40 to 40.99	1.02	50 to 50.99	1.22
41 to 41.99	1.04	51 to 51.99	1.24
42 to 42.99	1.06	52 to 52.99	1.26
43 to 43.99	1.08	53 to 53.99	1.28
44 to 44.99	1.10	54 and over	1.30

These prices are not to producer, buyers to pay salary or commission of their agents. In payment, 80% of estimated value of the ore (less moisture and freight from shipping point) to be paid against railroad bill-of-lading, with attached analysis, balance on receipt of ore by buyer.

The above prices are based on ore carrying not over 8% silica and 0.25% phosphorus. Bonuses and penalties are as under:

Bonuses	Penalties
SiO ₂ %	SiO ₂ %
Each 1% between 8 and 5% \$0.50	Each 1% from 8 to 15% \$0.50
Each 1% under 5% 1.00	Each 1% from 15 to 25% 1.00
	Each 1% from 20 to 25% 1.00

For each 0.01% in excess of 0.25% there is a penalty against unit price paid for manganese of 1/2¢ per unit figured to fractions.

Eastern Metal Market

New York, June 5.

Strength has developed in some markets in the past week, but there has been no pronounced activity in any. The tone is mainly firm, the only decline having appeared in tin.

Tin transactions and offerings have been very light and the downward tendency in quotations continues.

Conditions are unchanged for copper, which continues in heavy demand at Government prices.

Lead is fairly active, firm, and steady, with an advancing tendency.

Zinc is quite firm at unchanged price levels.

Antimony is lifeless, but no lower.

In the steel industry there is still a scarcity of steel for Government needs, though these are not fully known. Some days may elapse before a balance can be struck between the definitely scheduled demand the Government will make upon the steel industry for the rest of the year and the country's newly ascertained capacity in the various finished forms required. The committees are hard at work here and in Washington on this subject. New plans are in preparation for larger steel consumption, particularly in shipbuilding, both on this coast and on the Pacific. At the same time there are new reports of Government plans for laying hold of steel works, but the industry continues skeptical as to all such news, but is in no mood to do business except at the Government's bid. Pig-iron production in May, according to 'The Iron Age,' was at a rate exceeded but once in the history of the industry. The total was 3,446,412 gross tons, or 111,175 tons per day, while that of April was 3,288,211 tons, or 109,607 tons per day. The May output, with charcoal-iron estimated, was at the annual rate of over 40,900,000 tons, exceeding the high record of 39,434,000 tons in 1916. In October 1916, the record month, the daily rate was 113,189 tons. A feature of the output was the production of ferro-manganese and spiegeleisen, which made the surprising total of 54,633 tons, never before exceeded. About 33,000 tons of this was ferro-manganese, also a record.

COPPER

The principal topic in an uninterested market is the probable effect of the increased freight rates on copper costs. It is estimated that the new rates, effective June 25, will add an average of about 1c. per lb. to the present 23.50c. fixed maximum price. Opinions differ as to this, but where there is smoke there must be fire, and it is evident that some effect will follow from this source; how much, time will tell. One result of the coming higher rates has been an active demand on the part of consumers who have metal due them under contract to have as much copper shipped before June 25 as possible. The President has given his official sanction to the continuance of the present copper prices until August 15. What effect this will have on the small producer, especially in connection with the higher freight rates, is differently viewed, especially as to its influence on the output. Already six and possibly eight small mines in Michigan are seriously considering the necessity of closing on the ground that they are producing at a loss at existing prices. The Anaconda Copper Co.'s output in May was about the same as that in March, each month having 31 days for comparison. Exports for the first four months have been 122,106 gross tons, while the April exports are reported as 22,227 tons, the least for any month this year.

TIN

The market continues to sag in all positions, and buyers

are looking for still lower levels; therefore they are playing a waiting game. This tendency has been evident for some weeks. As a result the week has been dull and quiet, with practically no business transacted. There is an element of strength in the situation, however, due to a decided restriction and limitation in offerings. It is therefore probable that should buying movement develop, there would be a scarcity of tin, with a resultant general rebound in the market. This may take place at any time, but just when it is hard to guess. Whether the bottom has been touched no one knows, but it is the opinion of a large dealer that it will be a long time before 60 or 65c. tin will be seen again. Prices once more are lower, with spot-metal nominal at about 90c., New York, and future shipment from the Far East at about 85c., also nominal. The recent sinking of more than a dozen vessels in the Atlantic is disturbing to the tin trade, but so far no tin is reported lost. It is hoped that the worst is over. Arrivals at Atlantic ports in May were 846 tons, which is rather small for a month's receipts. The quantity in stocks and landing is put at 363 tons. Arrivals at Pacific ports are not reported. The London market continues to decline. Yesterday spot Straits was quoted at £346 per ton, or £9 less per ton than a week ago. The May average tin price at New York was nominal at \$1.01 per pound.

LEAD

Thus far this week there has been considerable enquiry, but it has not developed into large business at this writing, though it likely will. During the week, as a whole, as covered by this letter, the strength as noted last week has further developed, and the market is strong at about 7.20c., New York, or 7c., St. Louis, for early delivery. There have been no sales under the 7c. price of the American Smelting & Refining Co., and it is expected by some that this may be raised soon. The same feature, noted last week, continues to stand forth, namely, a scarcity of prompt lead. The exports in April were 5383 tons.

ZINC

The entire market continues strong but not particularly active. Quotations are firm and practically unchanged at 7.25c., St. Louis, and 7.50c., New York, for early delivery of prime Western, with third quarter held at 7.27½ to 7.50c., St. Louis, but not many willing to quote thus far ahead. No large sales have been reported, but inquiry is fair. The market may be described as quiet. The fact that there is a decided tendency to re-distill prime Western for conversion into grade A is regarded as a 'firming' influence on the prime-Western market, the production of which has probably been curtailed. Grade A is a big factor in war-work, and has been and is still heavily bought by the Government, which is also buying now more grade C than in the past. Exports in April are reported as 7290 gross tons.

ANTIMONY

Quotations continue unchanged at 12.25c., New York, duty paid, for prompt and early delivery, but demand is light. The Government is reported enquiring for a quantity for July delivery.

ALUMINUM

The price-fixing committee of the War Industries Board has changed maximum prices for No. 1 virgin metal, 98 to 99% pure, effective from June 1 to September 1, by adding 1c. per lb. to the former schedule. It now stands 33c. per lb. for 50-ton and larger lots, 33.10 per lb. for 15 to 50 tons, or 33.20c. for 1 to 15 tons. The same quotations are said to apply to scrap aluminum.

Company Reports

AMERICAN, ZINC, LEAD & SMELTING CO.

Property: large mines and mills near Joplin, Missouri, and at Mascot, Tennessee; also zinc smelters in Kansas, and a lead smelter in Missouri.

Operating Officials: H. I. Young, manager of Missouri mines; O. C. Burrell, manager of Tennessee mines.

Financial Statement: profits from operations in 1917 were \$1,694,551, plus \$85,613 from sundries. An agreement was made with Minerals Separation for flotation license and patent infringement, costing \$250,000. On deducting this the profit was \$1,530,163. Surplus at December 31, 1916, was \$4,904,316, and at end of 1917, \$4,594,497.

Dividends: on preferred stock amounted to \$483,238, and on common stock, \$386,240, equal to \$6 and \$2 per share, respectively.

General: since the United States entered the War the zinc industry has been greatly affected, due to less demand and attention to other essentials. At the end of 1917, 40 % of this country's retorts were idle, including many of the A. Z. L. & S. Co. The Mascot mines produce high-grade spelter suitable for brass in munitions, and all of the output has been sold. The company's natural-gas smelters in Kansas were closed, so it was decided to dispose of the American Pipeline Co., a subsidiary. Operations of the Granby properties in Missouri realized expectations. Although this company devised a flotation process, after Minerals Separation said that it would not be successful, it was decided to pay M. S. \$250,000 to settle alleged infringement of patents and become a licensee. The sulphuric acid works promise to be very profitable during 1918. The Wisconsin Zinc Co., a subsidiary, is making good progress.

BUNKER HILL & SULLIVAN MINING & CONCENTRATING CO.

Property: lead-silver mines, mills, and smelter in Coeur d'Alene region, Idaho.

Operating Official: Stanley A. Easton, manager.

Financial Statement: the revenue in 1917 totaled \$10,158,497, of which \$9,546,874 was from metal sold and \$469,980 dividends from the Caledonia Mining Co. Operations cost \$6,306,423, leaving a profit of \$3,852,074. Taxes—income and excess profits—were \$325,804.

Dividends: these amounted to \$2,043,750, making \$26,533,500 since 1890.

Development: Bunker Hill & Sullivan reports give little concerning the mines. The main shaft was sunk to No. 15 level, stations cut, and cross-cutting is well under way. Results on No. 14 level were most satisfactory, and indications for No. 15 are good. Reserves total 3,457,419 tons.

Production: the mills dressed 493,030 tons of ore assaying 10.6496 % lead and 4.317 oz. silver per ton. Recoveries were 89.51 % lead and 79.54 % silver. The yield was 93,992,898 lb. lead and 1,692,765 oz. silver. The output to date is 7,886,886 tons of ore valued at \$80,247,373, from which there was a profit of \$26,261,032.

Costs: these are always given in great detail, and briefly are:

Mines	Per ton 1917	1916	Mills	Per ton 1917	1916
Mining	\$2.385	\$2.364	Crushing and con-		
Tramming	0.058	0.059	veying	\$0.066	
Hoisting	0.056	0.054	Screening	0.041	0.045
Pumping	0.046	0.037	Jigging	0.078	0.073
General mine	0.590	0.560	Grinding	0.071	0.077
			Concentrating	0.161	0.100
			General mill	0.243	0.229

BUTTE & SUPERIOR MINING CO.

Property: mine and concentrating plant at Butte, Montana.

Operating Officials: J. L. Bruce, general manager; Charles Broeking, assistant and cashier; Angus McLeod, mine superintendent; J. T. Shimmis, mill superintendent.

Financial Statement: the past two years compare:

	1917	1916
Smelter settlements, less freight	\$6,716,437	\$13,141,551
Operating charges and special expense	4,368,941	4,349,420
Reserves for depreciation and depletion	1,941,130	2,508,047
Reserve for excess profit, etc.	236,647	
Net profit, plus other income	272,911	6,365,399

The surplus at end of 1916 was \$5,672,578. Adding the 1917 profit, and deducting adjustments and dividends, the surplus carried to 1918 was only \$651,721. Current assets are \$3,234,002, and liabilities \$482,331, both decreases. In consequence of flotation and mining litigation net earnings are now being deposited with the Court.

Dividends: four totaling \$5.40 per share amounted to \$1,567,057. Total to date is \$16,940,258, or \$59.65 per share.

Development: during June, July, and August operations were affected by labor troubles. A total of 17,730 ft. of new work was done, making 120,271 ft. of accessible openings, three shafts accounting for 5424 ft. The physical condition of the mine is better than ever. The completion of two new shafts have removed all trouble occasioned by the use of only one. On the 1900-ft. level ore of fair grade has been exposed. Reserves amount to 1,059,200 tons, assaying 17.6 % zinc and 5.9 oz. silver per ton, a slight increase in quantity.

Production: details appeared on page 764 of the 'Press' of June 1; but 461,953 tons, averaging 15.47 % zinc and 5.8 oz. silver per ton was dressed by concentration and flotation. This quantity was 25 % less than in 1916, due to suspension of operations. The mill needs few improvements in the future. Concentrates were sold to the A. Z. L. & S. Co., U. S. S. Co., and A. M. Co. They contained a total of 132,036,735 lb. zinc, 11,098,051 lb. lead, 1,329,570 lb. copper, 2,527,302 oz. silver, and 3918 oz. gold.

SHANNON COPPER CO.

Property: mines at Metcalf and reduction works at Clifton, Arizona; also control of Shannon Arizona Railway Company.

Operating Official: J. W. Bennie, general manager; H. H. Dyer, mine superintendent; W. H. Bond, mill superintendent.

Financial Statement: metals sold in 1917 realized \$1,824,947. Operations cost \$1,536,401, plus \$127,327 for special charges during the strike. The net profit was \$184,968. At end of 1916 surplus was \$1,337,771, but after paying dividends, depreciation, etc., the balance at December 31, 1917, was \$836,284. Current assets were \$486,087 above liabilities.

Dividends: four amounted to \$525,000.

Development: owing to strikes only 7 months work was done. Additional oxide ore continues to be uncovered, but became too poor to be smelted direct at a profit, so this is to be eliminated and only sulphide ore mined. A promising mine purchased in the Yeager Canyon district should commence producing by July 1918.

Production: 157,000 tons of company ore and 13,800 tons of custom ore yielded 6,138,219 lb. copper, 1096 oz. gold, and 51,771 oz. silver.

Costs: wages are 120 % higher than in 1914, fuel-oil advanced from 37¢. in 1916 to \$1.35 per barrel, coke is \$8.60 per ton, against \$3.75 in 1914, and lumber is \$10 per 1000 ft. higher.

REFERRING to the letter 'from the front' appearing in our last issue, we are pleased to say that we have received three offers to pay the subscription of the engineer-soldier who wrote that letter. We are glad to add that the matter already had been arranged in a satisfactory way.

ONTARIO has a number of new townships named after distinguished mining engineers and geologists, the christening having been performed by the Bureau of Mines in that Canadian province. Those whose names have been thus honored are William Frecheville, F. Lynwood Garrison, Alfred Harker, George T. Holloway, G. W. Lamplugh, Hugh F. Marriott, Charles F. Rand, and Bradley Stoughton.

BY resolution of the Board of Directors of the Institute, all members and associates that are enemy-aliens have been dropped from the roll. This will apply to three honorary members, Professors Beck, Schroedter, and Hoefler; also to 18 ordinary members in Germany. How many alien-enemy members there are besides those resident in Germany, we do not know. Professor Hoefler is the only member in Austria.

OUR news-columns have recorded the U. S. Supreme Court's decision affirming the judgment of the Nevada court in the case between the Jim Butler and West End mining companies at Tonopah. The Supreme Court decided (1) that the highest point of an anticlinal roll in a vein may be considered as an apex, vesting in the owner, therefore, the right to follow the vein on the dip in both directions outside the side-lines of the claim containing this so-called apex; and (2) that the broken end-lines in the West End claim do not bar the exercise of such extra-lateral rights. The decision is one of far-reaching importance; we consider it most unfortunate, because it reduces the law of the apex to an absurdity. At an early date we hope to publish some further remarks on the subject.

IN our news columns of May 25 it was reported that a standardized method of assaying drill-cuttings was to be adopted in the Komspelet region. So many systems were used that it was difficult to tell how to appraise the results. Recent advices state that twelve of the leading

assayers in the region have formed a committee to standardize the method of assaying zinc ore. Mr. W. G. Waring, well known at Joplin, is chairman. A report will be made at an early date. Incidentally, the Tri-State Mine Safety and Sanitation Association, through its chairman, Mr. Temple Chapman, at Picher, Oklahoma, gives some interesting figures on the cost of producing zinc and lead concentrate in the Komspelet region. The cost is as follows: mining and milling, \$38; royalty on leases, \$8; depreciation and depletion, \$10; making a total of \$56 per ton. The value of the product shipped last week was \$50, showing a loss of \$6 per ton on the production; but we presume that this depressing estimate of cost was made with an eye to melting the hard hearts of the price-fixers at Washington. However, we appreciate the difficulties of the zinc miners; they have suffered keenly from the effects of delay in governmental action.

STANDARDIZATION of mining statistics is the subject of Technical Paper No. 194 just issued by the U. S. Bureau of Mines. The compiler is Mr. Albert H. Fay, whose name is familiar in connection with the kind of publications that are usually deemed arid, although they are fertile in suggestion and generalization to those that know how to "read, mark, learn, and inwardly digest them" without suffering from mental dyspepsia. Speaking seriously, this report was prepared on the initiative of a committee appointed by the U. S. Bureau of Mines in February 1916 at a meeting of State mine inspectors and representatives of industrial-accident compensation commissions. At that time twelve standardized forms were presented for discussion, and Professional Paper No. 194 embodies the points that were brought out during that discussion. It is now submitted with the hope that it may be adopted by those that were originally consulted and by others engaged in similar work. The need for standardization is obvious to those whose duty it may be to co-ordinate data from the reports issued in various States. We commend both the pamphlet and the motive that brought it into existence.

CALIFORNIA, says Mr. Ralph P. Merritt, in proportion to her population, is shipping more food to Europe than any other State in the Union. We are proud of that. The United States is feeding 120 million people

in Europe in addition to the 110 millions in this country, and this *ravitailement* is being effected despite a decrease of 11 millions in productive man-power. Of the 170 million bushels of wheat to be shipped to Europe from the 1917 crop all but 20 million bushels is due to the voluntary conservation of the American people under the leadership of Mr. Herbert C. Hoover. Last month 300 million pounds of hog products and 140 million pounds of beef were forwarded to Europe, and these totals will be more than maintained until victory releases our Allies for the production of their own food-stuffs. It is highly satisfactory to note how completely the Food Administration has won the national confidence. This is greatly to the credit of the Administrator, Mr. Hoover, who began his task under enormous difficulties but has won support by his sincerity and ability. That ability has been shown in his choice of lieutenants. The public in California recognizes in Mr. Merritt a man peculiarly fitted to be State Director and is glad to stand by him in the fulfillment of his difficult duty.

VENEZUELA has been heard from. The silence of the press regarding that republic has long excited suspicions that something was wrong. It argued a control upon the news at its source, and the fact that the Krupps and the cartels linked to them had long been prominent in Venezuelan financial and commercial circles left little doubt as to the dominating influence. Señor Carlos Lopez Bustamante has reached New York with a tale of imprisonment at Carácas, the capital, for daring to publish editorials favoring the Allies. After eight months he escaped and was smuggled on board a ship bound for the United States. He hints at a possible U-boat base on the Venezuelan coast, which could mean only the gulf of Maracaibo. That seems hardly likely, because the entrance would be relatively easy to guard by our warships stationed near-by at the Panama Canal. We think there are greater possibilities of hiding in the intricate system of lagoons and coral islands along certain parts of the western shore of the Caribbean. Nevertheless, it will be well to keep a close watch upon President Juan Vicente Gomez, who rode into office on horseback in the customary melodramatic manner, and must needs have his reward. Incidentally, the Barber Asphalt Company, in Venezuela, may at last take action to itself for having been beaten by the Germans in winning favor with the authorities at Carácas.

GREAT dissatisfaction pervades the world of copper-producers. Rising prices of commodities have involved a large increase in the wages paid, all supplies have advanced from 50 to 200%, and the cost of producing the metal has grown in proportion. The copper market is suffering as are all markets that are 'regulated,' because regulation has not at the same time protected them from the exorbitant prices current in the industries that are still free from Government control. The latest suggestion is reported in our New York metal-market letter this week. Some one in Washington has hinted at setting apart 15% of the output to be sold in an open

unrestricted market, the remaining 85% to be distributed under Government orders at the price of 23.5 cents. We do not believe this will prove more pleasing than the existing arrangement. It will introduce feverish speculation, which is altogether undesirable at this time; it will seriously affect many manufacturers working on orders from private corporations, such orders in reality constituting part of the work needed under contract to the Government. It is almost impossible in these days to disentangle production for the people at large from that required in the military activities of the nation. Juggling with prices is a dangerous thing, except on the basis of a single rule for all. The fruit of cultivating an economic fallacy is a harvest of errors that furnishes seed for increasing crops of evil.

PRESIDENT FAUNCE of Brown University has stated recently that we are fighting "the power of misapplied science." All our dreams of a world to be rendered more pleasantly habitable by grace of scientific discovery have been shattered by the beast with the brains of an engineer. He has prostituted science to piracy, and invention to the filthy cruelties of an Apache. War used to be limited in its calamitous scope, first, by a sportsmanship expressed by chivalry, and, second, by the fact that it was waged by relatively small armies of professional soldiers, leaving the nations not only as backers whose fortunes were determined by the result of the contest but as peoples detached from the fighting itself, even in case of invasion. Now whole nations are fighting, the entire physical and industrial resources of the leading peoples of the earth are being pitted against each other, and the imminence of a prolonged, cruel, and devastating war is being brought home to every fireside in the civilized world. The Germans are waging unlimited war, unlimited in its use of every resource, unlimited in its disregard of every convention, decency, or morality. Science has been mobilized by them to the fullest extent in order to kill, maim, or poison those whom they have attacked wantonly in their highly organized purpose to win world dominion. Atrocities are concocted in the laboratory, murder is designed by strictly scientific method, poisoning is planned by chemists and bacteriologists, demoralization of the enemy is devised by psychologists. Science has been forced to play the dirtiest game in all history. And the Allies must retaliate. The cruelty of any war is determined by the most cruel of the contestants, because, unfortunately, there is no way to check cruel methods except by others like them. The desperado must be killed, the spy must be shot, the user of poison-gas must be driven back by a more deadly gas, the submarine must be sunk by the depth-bomb. Chivalry has been destroyed. The Hun sneers at "slave morality" and glorifies "the will to kill." *Habet*. We must meet him on the ground he has selected, beat him by his own scientific method, but always disdaining to use the obscene cruelties and the filthy bestialities that he, led by a military caste without a sense of honor, has introduced into warfare.

Flotation Litigation

It is announced that the Minerals Separation company has decided to take an appeal to the United States Supreme Court from the recent decision of the Ninth Circuit Court of Appeals in the Butte & Superior case. This appeal will probably be heard at the October term. In issuing its decree the Appellate Court made an extraordinary blunder, as our readers are aware, in assuming and stating that the Butte & Superior company had never used less than 0.5% of oil per ton of ore, whereas the fact, as stated clearly in the briefs and in the pleadings of both parties to the suit, was that the Butte & Superior company had used more than 0.5% only since January 7, 1917, that is, immediately after the U. S. Supreme Court, in its adjudication of the Hyde case, had restricted patent No. 835,120 to the use of a critical proportion of oil as described in the testimony and in the patent. If the Appellate Court in San Francisco had not corrected its decree, the decision would have been reversed or at least modified by the Supreme Court, although the error made was a plain oversight of admissions appearing in the record and conceded by both litigants. Next arises the question: What will the Supreme Court do? First comes the petition for a writ of certiorari to be presented by the loser in the recent appeal in San Francisco. As a matter of statistical average it can be stated that of such petitions for a review only one in six is granted. The right of ultimate appeal follows as a matter of right whenever a question involving the interpretation of Federal law appears in the face of the complaint. No such question arises in the case under discussion; but another reason for a review before the Supreme Court is "a principle of far-reaching importance," which apparently does arise in this instance and which may therefore cause the Court, as a matter of grace, to issue certiorari. Again, the Butte & Superior case involves an effort to interpret a previous decision of the Supreme Court in a similar controversy, namely, the Hyde case. It is customary for the Supreme Court to grant a review if it is necessary to clarify the effects of its previous judgment. Moreover, a conflict of decision between two courts of appellate jurisdiction, such as has arisen between the Third Circuit Court of Appeals in the Miami case and the Ninth Circuit Court in the Butte & Superior case, would be deemed to justify the granting of a petition for a review. In the main, it may be said that the Supreme Court can do, and does, as it pleases, but it has itself laid down sundry rules of procedure as we have outlined. Under the circumstances it is vain, if not unseemly, especially for those unversed in legal matters, to forecast the outcome of a petition for certiorari to be presented, as we are informed and as was to be expected, by the Minerals Separation company. If a review be granted then it would appear likely that the Supreme Court would sustain the opinion of the Appellate Court because the opinion seems to be a logical sequel to its own dictum; in short, the Supreme Court may consider

the recent decision in accord with its previous judgment. The fact of there being a dissenting opinion would be disregarded. We wonder what the Supreme Court will think of the insistent assertion, by Minerals Separation in the Hyde case, that the success of experiments made with an excess of oil was due to laboratory tricks such as could not be confirmed on a working scale, having regard to the fact, now affirmed in the Butte & Superior record, that mills were getting an excellent metallurgical result at the rate of 1000 tons per diem within 60 days after the decision in the Hyde case was published. The Miami case is now in the stage of proceedings for an accounting. In the event of a disagreement over this accounting there may at any moment arise a need for an appeal to the Third Circuit Court of Appeals at Philadelphia, and eventually the Miami case also might be brought before the Supreme Court. A similar accounting for infringement before January 7, 1917, will be made against the Butte & Superior company, but punitive damages, we understand, are not collectable by Minerals Separation, despite sundry threats to do so. The measure of damages will be the difference in profit as between the use of the patent infringed and the nearest alternative process. Here also a dispute may necessitate further reference to the Court of Appeals. The litigation is by no means at an end, but it is approaching a logical conclusion.

An Expanded Monroe Doctrine

Comment upon the remarks made by the President the other day to the Mexican editors that are touring the United States has assumed too hastily that a promise of non-intervention under any circumstances was implied. We fail to find warrant for construing the words of the address in that sense. We must recall that confidence in the reasonableness of Germany, and assurance of our willingness to maintain amicable relations with her, colored every communication sent from Washington up to the one that carried the thunderbolt of outraged humanity. It is not the custom of those versed in statecraft to use the blunt phrases admissible in common speech. Mr. Wilson now reiterates the kind feeling of America toward Mexico, the proofs of which have been accumulating through the past eight years, and he directs attention to supreme examples of our unselfish efforts to promote the welfare of that country, while at the same time he intimates delicately how our acts have been misinterpreted. He re-affirms our earnest desire to co-operate with our neighbor in a friendly manner, but he also refers pointedly to the German activities permitted under shelter of the Mexican flag, which have become increasingly aggravating since we entered the War. The President's utterance is diplomatic, and he makes excellent use of innuendo to convey a warning the significance of which will not be lost upon a people accustomed as are the Mexicans to subtle suggestion in their speech. At the same time he gives assurance of our desire to live on terms of cordial fraternity with Mexico and to safe-

guard not only her territorial integrity but that of every other republic in the western hemisphere. Thus he has expanded the Monroe doctrine into a declaration of national rights to be respected as much by ourselves as by empires across the seas. This is the answer given to Carranza's appeal to the other Spanish-American countries that they adopt a 'neutrality' of a sort that would exclude commerce with us and our Allies while the blockade against Germany existed. This is the reply to the insinuations in Señor Cándido Aguilar's note to Cuba that she is a bond-servant of the United States. In the face of the President's declaration, which puts the bar to our further territorial growth in the Americas, Carranza will recognize that the inalienable rights of his country have received the stamp of formal recognition by the United States, and he will not fail to note that the counterpart to every right is a corresponding duty.

A 10% Tax on Commodities

REPRODUCED BY PERMISSION OF THE AUTHOR

The report on commercial bribery submitted to Congress last month by the Federal Trade Commission should have awakened an instant response. It touched one of the cankers of modern trade; it revealed how business in the United States has suffered from a monstrous evil, preventing the proper flow of trade on a genuinely competitive basis, increasing the cost of nearly every article of commerce by 10% or more; and it showed that the vice of commercial bribery in this country had been turned to account by the Tentons before the War in an effort to enslave the American to German manufacturers. Since the outbreak of hostilities the corrupt practice has been continued by hyphenated firms and corporations, one object of which evidently is to keep these people in line for readier dominance . . . in the event of certain catastrophies to American arms that aren't going to happen. We have been surprised that Congress received the report with so little sign of interest. Indeed, barring sundry remarks by Senators Brandegee of Connecticut, Smith of Michigan, Johnson of California, and Chamberlain of Oregon, Congress has done little that was spontaneous and refreshing for many months. More than this, no real publicity has been given to so astounding a report prepared by one of the most important commissions in the country. The almost universal silence after it appeared was as remarkable as the revelations in the document itself. At a time when gold mining is nearly crushed by exorbitant costs while the commodity-value of the output is approximately 48% less than its nominal value; when the Chino company reports an increase of 126% in three years in the cost of its copper, closely followed by Utah Copper with 113%, and Nevada Consolidated with 81%; when mining has been rendered so precarious that guaranteed markets have become essential to the existence of many branches of the industry; when these conditions threaten an adequate response to the national need for mineral products, it would be a great boon to follow the recommendation of the Federal Trade Commission, and enact

legislation to stamp out this iniquitous graft. To do so would result in lowering the average cost of manufactured commodities by 10%. The report of the Commission says, "These bribes take the form of commissions for alleged services, of money, and gratuities and entertainments of various sorts, and of loans—all intended to influence such employees in the choice of materials. . . . Corrupt employees having the power to spoil and disapprove materials have been able to bid one salesman against another until in many cases they have extorted secret commissions, so-called, as large as 20% of the value of the goods sold." In another place the report declared, "It is useless to discuss the origin of the practice. It is sufficient to know that it exists generally and appears to be spreading . . . that it must engulf even those honestly inclined if they desire to maintain their commercial life. . . . It should also be noted that the practice appears to have been most general on the part of concerns in introducing the goods and wares of German firms. Among such concerns and their salesmen the evidence is that the practice is recognized as a legitimate method of competition."

This is enough to justify the people in demanding that Congress make haste to pass the bill introduced into the Senate by Mr. Albert B. Cummins for carrying into effect the recommendation that such a measure was required "in the public interest as an aid to the preservation of fair and free competition, striking at the unjustifiable and vicious practices of commercial bribery."

Every mining engineer that has charge of extensive operations can cite mystifying instances where drill-steel that he knew to be sound was condemned as a failure by his drillers and his tool-dressers; where a brand of lubricating oil that he had found eminently satisfactory elsewhere persistently gave poor results in his new mill, while another brand that he believed to be inferior suddenly produced an effect that by contrast was marvelous. We have all seen examples of the concentrator that would not treat its full load of pulp without losing its powers of discrimination between mineral and gangue, while a machine, based on the same mechanical principles, but in an altered form, would render creditable service, although these conditions were exactly reversed in the mill across the canyon. The excuse of a subtle difference in the ore is not always the correct explanation. The exposition of corruption that has just been made by the Federal Trade Commission comes nearer to offering a solution of the puzzling behavior of well-known brands of steel and oil, of picks and shovels, and car-wheels, and the mysterious superiority in the steaming power of certain coals over others that the foreman rejects despite their higher proportion of fixed carbon and their lower content of ash. Thirty years ago the bribery of managers by purveyors of mine equipment was nearly universal, but the gradual substitution of the trained engineer for the 'rough-neck' brought with it a reform. Truth and honor are allies, and the scientific training inculcates respect for the actualities that are revealed in

scientific study and research. The habit of looking for and stating the truth develops in the engineer a fine sense of rectitude, quite apart from any special moral culture that he may have received, and this has done much to elevate the tone of the mining business. The selling agent that would practice commercial bribery is afraid to visit the manager's office today with insinuations of easy money to be had by putting corrupt self-interest ahead of duty to his company. The mining engineer stands for a higher code of ethics, and is eager to support legislation that will help him to conduct his business in a clean way without interference from bribe-givers and bribe-takers. He will stand on the side of those who realize that graft must be eliminated, and that if these and other means be not taken to reduce or to equalize the costs of commodities, financial disorders will presently embarrass the Government and the people. We may differ as to policy, but Americans will be a unit in demanding a clean government and a clean commercial life. This Teutonic method of doing business was prohibited in Great Britain by Act of Parliament as much as 20 years ago; there is no reason for our failing to do likewise, for we are at heart an honest nation. The bill should be passed at the present session of Congress.

Pulverized Coal

The restriction upon industry resulting from the difficulties of mining and transporting the large quantity of coal demanded by manufacturers must be relieved by utilizing every possible resource. Mechanical efficiency, giving higher returns in power delivered per unit of fuel consumed, is as much a resource as the development of more coal. In another column we print an article by Mr. W. G. Wilcox on the use of pulverized coal. The subject is attracting greater interest every day. The idea is not new; in fact, powdered fuel has been used to a considerable extent for twenty years or more. It was applied long ago to the burning of cement-clinker in rotary furnaces, and was found to yield superior results. A long flame is detrimental to the successful burning of the 'mix,' and coal-dust admits of perfect combustion close to the jet delivering the air and the fuel. The construction of the long rotary cement-kiln made it imperative to accomplish this result, for if the combustion does not take place at once, a long smoky flame will extend throughout the length of the kiln, since air cannot be introduced at other points than the firing-end of this apparatus. It is surprising that so much hesitation has been displayed in adopting pulverized coal for boiler firing, but manufacturers are inclined to be slow in departing from the conventional paths. The exigencies of war, however, are compelling a more scientific application of fuel, and this improvement offers a means for relieving the stringency caused by a lack of sufficient miners and of adequate facilities for transportation. Thus war, with its ruthless waste and destruction, draws in its train economies that will persist in our industrial life, and aid in the solution of urgent problems of conserva-

tion. One notable achievement in the use of powdered coal has been seen recently in copper metallurgy. The principle of burning fuel so that it is nearly all converted into carbon dioxide close to the jets, producing a short hot flame, is revolutionizing reverberatory practice. Furnaces built with a rated capacity for smelting 500 tons of ore per day now smelt twice that amount, without necessitating any structural changes. The settling of the matte from the slag is improved, and the heat-recovery by water-tube boilers in the flue is as good as under the old system of firing. The principle is applicable whether oil or coal be used as fuel, but it is more effective with pulverized coal. At the Steptoe plant of the Nevada Consolidated Copper Company this system was introduced in April, resulting in the conservation of approximately 1400 barrels of oil daily, based on the increased tonnage of ore that could be smelted. It was also found to be possible to treat a more refractory charge than when firing was done with oil, and a better distribution of heat in the furnace was obtained. The dried pulverized coal is fed into the suction of a series of fans, which deliver it through a 'pipe-header,' the ratio of 50 cubic feet of air per pound of coal being maintained. The total saving in cost is said to be quite large. Mr. Wilcox in his article points out that the rate of combustion depends upon the total surface of coal exposed to the air at a temperature high enough for instant ignition, and as the specific surface is increased by fine grinding the condition for rapid and perfect combustion is thereby improved. This, however, is only part of the story. His statement that, by comminution, "we have changed entirely the characteristics of coal as commonly known" is extremely significant. Pulverization reduces a considerable proportion of the coal to a degree of subdivision so minute as to bring it within the colloid realm. This partly explains the fact that it burns in a manner analogous to gas, for a colloid consists of but a few molecules, and a colloid particle behaves similarly in many respects to the individual molecule, such as exists in a gas. Furthermore, the greater the specific surface of a solid the greater is its power of adsorption for gases, and carbonaceous colloids are remarkable for the quantity of oxygen that they adsorb from the air. On account of its minutely cellular structure, ordinary charcoal adsorbs 9½ times its own volume of oxygen, and the quantity adsorbed by colloidal charcoal is much greater. Coal does the same thing, though to a somewhat lower degree than charcoal, but herein lies the explanation for the extraordinary approximation to the theoretically perfect combustion that is obtained by the use of this pulverized fuel. A great store of oxygen is condensed upon the colloidal particles ready to effect instantaneous and complete combustion on being brought into the high temperature of the furnace. Where the object is to secure the highest possible temperature with the most economical consumption of coal no other method of burning should be employed. It saves money, saves man-power, saves railroad equipment, and helps to carry to a successful conclusion our paramount business of crushing Germany.

Table for Sulphidizing Solutions

By K. B. THOMAS

Sodium sulphide is being used in a number of plants for sulphidizing ores for flotation, and the practice is growing rapidly. Recently I learned from an operator who is thus employing sodium sulphide that his custom in preparing the solutions is to make them up and then determine the percentage of Na_2S present in them. This work could be eliminated by means of the table given herewith, which I had occasion to prepare a short time ago, from solutions of the commercial sodium sulphide.

Degrees Baumé	Sodium Sulphide Liquor Grammes Na_2S per 100 gm. solution	Na_2S %	Na_2S per cu. ft. of solution, %
1.0	0.953	0.85	0.59
2.0	1.166	1.15	0.73
3.0	1.582	1.55	0.99
4.0	2.107	2.05	1.31
5.0	2.692	2.60	1.68
6.0	3.337	3.20	2.08
7.0	3.990	3.80	2.49
8.0	4.655	4.40	2.81
9.0	5.330	5.00	3.33
10.0	6.068	5.65	3.79
11.0	6.762	6.25	4.22
12.0	7.573	6.95	4.73
13.0	8.235	7.50	5.15
14.0	9.021	8.15	5.63
15.0	9.953	8.90	6.20
16.0	10.790	9.60	6.74
17.0	11.724	10.35	7.32
18.0	12.552	11.00	7.84
19.0	13.512	11.75	8.44
20.0	14.442	12.45	9.02
21.0	15.547	13.30	9.71
22.0	16.504	14.00	10.31
23.0	17.642	14.85	11.02
24.0	18.629	15.55	11.65
25.0	19.811	16.40	12.38
26.0	21.010	17.25	13.13
27.0	22.080	18.05	13.80
28.0	23.788	19.20	14.87

The above are all on a basis of solution at 60° F. For the difference in temperature the correction in Baumé should be made as follows: Add 0.1 degree Baumé to the reading for each 4 degrees that the solution is above 60° F. For example: If the solution tests 12° B. and 100° F., then $100 - 60 = 40 \div 4 = 10 \times 0.1 = 1.0$. The true Baumé reading then is $12 + 1 = 13^\circ \text{B.}$ at 60° Fahrenheit.

REACTIONS of hydrogen peroxide were investigated recently by V. Maeri ('Boll. Chim. Farm.'). While the reactions of $(\text{NH}_4)_2\text{MoO}_4$ with H_3PO_4 and H_2O_2 , respectively, are sensitive and characteristic, H_2O_2 prevents the precipitation of NH_4 phosphomolybdate, coloring the solution intense yellow. The reaction of H_2O_2 and CrO_3 is not inhibited by the presence of H_2S , provided the CrO_3 solution is poured into the H_2O_2 - H_2S solution. H_2O_2 in the presence of CaCl_2 and NH_4OH causes the formation of a white gelatinous precipitate, which increases with time, and finally changes to an amorphous, heavy, pulverulent deposit; this precipitate is composed of CaO_2 and is soluble in AcOH , from which it is not re-precipitated by addition of NH_4OH . When evaporating H_2O_2 in a platinum dish in the presence of HCl , H_2PtCl_6 is formed. H_2O_2 does not appreciably decompose KMnO_4 in the presence of HNO_3 (instead of H_2SO_4 , HCl , etc.); decomposition, if it occurs, commences only

after a considerable length of time; the decomposition proceeds more rapidly as the amount of KMnO_4 is increased. The amount of free acid (this method was only tested with H_2SO_4) in a H_2O_2 solution, may be determined by adding a standard solution of KMnO_4 , with constant agitation of the acid H_2O_2 solution, until the latter assumes a brownish-yellow color. This determination is based on the fact that pure H_2O_2 does not decompose KMnO_4 , and the amount of KMnO_4 decomposed by an acid solution of H_2O_2 is proportional to the amount of acid present. The content of acid may be calculated from the amount of KMnO_4 consumed, according to the equation:

If the amount of acid present is very small the change in color is detected with difficulty. The addition of a small amount of MgSO_4 renders the color change more distinct.

Mexican Metal Production in 1917

The following statistics of metal production in Mexico for the year 1917, are furnished by the Statistical Section of the Department of Mines of the Republic. The quantities given are in kilogrammes (1 kg. = 2.2 lb.).

Gold		Kg.
State		
Aguascalientes	652,000
Coahuila	365,000
Durango	161,313
Guanajuato	9,358
Hidalgo	1,855,707
Mexico	2,124,737
Nuevo Leon	289,623
Puebla	6,000
Sonora	240,234
Zacatecas	85,000
Total	5,788,972

Silver		Kg.
State		
Aguascalientes	103,255,650
Coahuila	76,255,000
Durango	16,490,500
Guanajuato	744,000
Hidalgo	336,160,604
Mexico	14,588,189
Nuevo Leon	40,663,320
Puebla	85,000
Sonora	42,873,102
Zacatecas	17,572,000
Total	618,684,365

Copper		Kg.
State		
Aguascalientes	4,371,297
Baja California	8,225,000
Coahuila	644,000
Nuevo Leon	31,089,484
Sonora	83,248,000
San Luis Potosi	565,590
Zacatecas	12,285,595
Total	141,528,966

Lead		Kg.
State		
Aguascalientes	541,611
Coahuila	11,308,000
Durango	6,099,503
Nuevo Leon	7,523,252

Total	29,769,455

Zinc		Kg.
State		
Zacatecas	3,888,124

Antimony		Kg.
State		
San Luis Potosi	2,140,590

The Use of Powdered Coal

By W. G. WILCOX

*Power and raw materials are the two factors that make up the balanced ration of industry. No matter how great our national resources, they will be of little value unless the power necessary for transportation, manufacturing, and fabrication is available. The greatest source of power is obtained through the combustion of fuels. Shortage of fuel at this time is so alarming as to call for the most careful consideration. The production scarcely equals the consumption. Concomitantly with the greatest demand for coal we have ever experienced we find the great natural gas-field of West Virginia failing alarmingly. This brings into the list of coal-consumers new users that were formerly dependent upon natural gas. At the same time fuel-oil is steadily becoming harder to obtain and almost prohibitive in cost. The oil-fired forge-furnaces of the East and the copper-reverberatories and cement-kilns of western Texas, Arizona, and Utah, the potash-producers of Nebraska, and the apartment-houses of Seattle are seeking supplies of coal. This means another new demand and a further burden on railroad transportation. As the railroads must have more coal in order to haul more coal the seriousness of the situation increases geometrically.

For this exigency there are three possible solutions:

1. Stimulation of the production and transportation of fuel.

2. Development of efficient methods for utilizing low-grade fuels hitherto practically unused.

3. Combustion of the fuel in so much more efficient a manner as to make the amount available adequate for all needs.

At best there does seem little reason to expect a great increase in production. Our largest opportunity for escape from the dilemma lies in the efficient combustion of both low-grade and high-grade fuels. It is far wiser to curtail avoidable losses than to compensate for them by increasing the supply. It is pre-eminently the patriotic and professional duty of the chemist and the engineer to work for the more efficient utilization of fuel. Among the more efficient methods of combustion is the use of powdered fuel. Assuming a good design of furnace and flue, and the proper draft, the essentials of good combustion for coal are:

1. Complete oxidation of all the combustible matter in the coal to avoid loss of combustibles in the ash and up the stack. The loss of unburned carbon will vary with different types of fuel, with different types of ash,

and with the percentage of ash in the coal. It will also vary with the type of stoker used and the boiler load carried. In hand-firing it will vary with the skill of the fireman; and in producer-operation it will vary according to the quality of the coal, the type of the producer, and the operating conditions.

Using an Illinois coal of the following analysis:

	%
Sulphur	5 1/2
Volatile matter	34
Fixed carbon	42
Ash	18 1/2

one of the large users in the Middle West records the following losses in ash:

	Actual per cent of coal lost
Over-feed stokers, 25% unburned carbon in the ash	4.6
Chain-grate stokers, 35lb unburned carbon in the ash	6.5
Hand-fired, 35% upward unburned carbon in the ash	6.5 and upward

This particular consumer has two different types of stokers and also does a large amount of hand-firing. His consumption is over 100 carloads of coal per day; operations are under the direction of skilled technical men.

In producer-operation, using a good-grade coal, 20% of unburned carbon in the ash is the minimum figure. Under bad conditions, when poor fine wet coal was used, and with variable steam-pressure, as high as 55% unburned carbon will be found in the ash even with a first-class modern producer.

With any type of stoker or producer the loss due to unburned carbon increases with the ash-content. Certain coals, although of high heating value, present enormous difficulties to efficient operation when put through a producer, or when burned on grates or on stokers. A case in point is a coal from south-western Virginia. This develops over 14,000 B.t.u. and contains under 8% ash; it shows fine laminations of pure calcite in amount sufficient to flux the other constituents of the ash and cause continuous trouble from clinkering.

Another case is a Colorado coal having the following proximate analysis:

	%
Ash	6.66
Volatile matter	43.76
Fixed carbon	49.58
Sulphur	0.93
B.t.u.	12,886

The ash melts, runs down the grates and freezes there, while the coal itself disintegrates, and chokes the fire.

*Paper read before the Western New York section of the American Chemical Society, May 31, 1918, by the Advisory Engineer to the Powdered Coal Engineering & Equipment Company, of Chicago.

2. Control of combustible and air. This is absolutely essential if we are to secure the maximum flame-temperature with a correspondingly increased rapidity of heat-transfer. The more rapid the transfer of heat in the furnace or boiler the higher the capacity of the furnace, and in general the greater the efficiency.

3. Control of flame-length. In order to maintain the conditions that the design of the furnace, the operation, or the metallurgical process, requires, it is essential that the length of the flame be under control. An example is found in a recent development in firing copper reverberatory furnaces. For a long time it has been the practice to fire such furnaces with an insufficient amount of air, admitting the amount required to complete combustion through ports in the side of the reverberatory. It has been found that if the number of oil-burners is increased, and the mixture of oil and air so adjusted as to give complete combustion with a short hot flame, the capacity of the furnace is increased in some cases as much as 50%, while the fuel ratio is greatly improved. This is also true of reverberatories fired with powdered coal. In this particular operation it has been found that a short hot flame leads to more efficient operation and increased capacity; but there are other processes in which the reverse is true.

In changing the fuel, for example, in turning from the hand-firing of coal to powdered-coal combustion, the economies are usually far greater than those that can be figured from the known losses. The increase in capacity is usually so great that it can only be attributed to the increased efficiency of the furnace. This may follow from the fact that the operator is enabled to maintain the flame-length and type of combustion for which that particular furnace is suited.

4. The method of combustion that is to be most efficient must possess flexibility in capacity. Flexibility in combustion means rapid response. Only in this way can a cold furnace be brought to heat quickly or a stand-by boiler come up to peak-load rapidly. This makes for efficiency because it reduces the fuel consumption during the stand-by period. Many operations also require variation in heat input at different stages; in order to secure the highest efficiency under these conditions, extreme flexibility as to 'combustion load' is demanded.

5. Control of the nature of the combustion. In many operations it is not only necessary to heat uniformly, quickly, and efficiently, but it is equally important to maintain a certain chemical condition in the atmosphere of the furnace. This may be oxidizing, reducing, or neutral. In any case the control of combustion should be such that the desired condition may be maintained within close limits; failure to do so means a waste of fuel. Maintaining an oxidizing condition without ability to control it within close limits will result in an excess of air, which will lower the flame-temperature, lessen the output, lower the furnace efficiency, and reduce the fuel-efficiency. Likewise a reducing condition, unless maintained within close limits, means that fuel is needlessly wasted. If the operation demand a neutral condition,

there may be some loss due to the spoiling of the product, unless it be possible to maintain the neutral condition exactly.

6. One-stage combustion. The best example of two-stage combustion is the producer, which in many of its applications affords an over-all efficiency that is considerably higher than may be obtained by other methods. Nevertheless we should realize that in the process for making producer-gas there is an inherent loss of at least 20% because of the inability to gasify without forming a certain percentage of CO_2 , due to heat-losses at the producer and losses in sensible heat from the gas between the producer and the point at which it is used.

There is another serious objection to two-stage combustion. When combustion is completed, the final flame-temperature is lower than in a one-stage process. Unless we resort to such devices as the recuperator or regenerator, high temperatures cannot be reached. Furthermore a two-stage combustion results in 'cracking' some of the most valuable constituents of the coal, with the formation of smoke in the furnace and soot in the producer. This has been shown by Kreisinger, Augustine, and Ovitz, in Bulletin No. 135 of the U. S. Bureau of Mines.

Having considered the essentials of combustion, we can estimate the value of powdered coal as a fuel. In the same way we can ascertain also the conditions demanded for success in the combustion of pulverized fuel.

The simplest view of the combustion of coal is to regard it as a reaction between fuel and oxygen. It is a heterogeneous system; consequently the velocity of the reaction and its completeness will depend upon the surface exposed by the solid, the pressure of the reacting gas, and the intimacy of the mixture. By grinding an inch cube of coal so fine that 85% will pass a 200-mesh screen, we have increased the surface exposure from six square inches to approximately 1800 sq. in. Thus we have increased the velocity of combustion 300-fold. By doing so, we have changed the characteristics of the fuel. We now have a fuel relatively 300 times more active than the inch cube of coal, a new type of fuel that has in it inherent possibilities not to be found in lump or slack fuel. By increasing the surface exposure 300-fold, we have speeded combustion proportionately. This carries with it a further effect. The increase in rapidity of combustion also increases the rapidity of heat evolution, and consequently quickly raises the temperature of the rest of the material. This rise of temperature, which is much more rapid than in the normal combustion of coal, will double the velocity of combustion for each rise of 10°C . The increased rapidity due to greater surface exposure and that due to temperature rise are superimposed so that a pulverized fuel affords a combustion that is hundreds of times faster than when burning lump-coal.

Having a finely-divided fuel it is possible to form a mixture of fuel and air so intimate that each small particle of coal is surrounded by the proper amount of air. In this condition, by maintaining the proper velocity of

PLATE-HEATING FURNACE SHOWING POWDERED-COAL FEED-PIPE AND CONNECTIONS TO BURNERS

DISCHARGE END OF CONTINUOUS-BILLET HEATING-FURNACE

the air-current, the fuel can be carried into the furnace in suspension and there burned completely, efficiently, and rapidly.

It is, of course, a simple matter to mechanically control the amount of powdered coal delivered to the furnace in a given time. It is also possible to control the amount of air delivered with the coal. If, then, we deliver to the furnace an intimate mixture of air and powdered coal, and control the amount of coal-dust and air delivered, we have the prime essentials. The degree to which they are attained depends entirely upon how carefully we study the characteristics of the fuel before and during combustion.

The amount of coal-dust delivered can be controlled simply and positively by using a screw-feeder operated at variable speed. It is also a simple matter to control the volume of air admitted with the fuel; but the highest efficiency possible with this type of fuel will not be obtained unless we work out a correct way in which to mix a finely divided solid with the air.

A study of the methods for making such a mixture immediately shows that the methods commonly used in making a uniform mixture of two miscible liquids or a uniform solution of a solid in a liquid, or the methods used in mixing finely-ground solids are not only useless in this case, but will actually separate the coal-dust from the air. Ordinary mixing is done by agitation; this agitation is usually accomplished by baffling, stirring, shaking, or similar devices. When, however, such methods are applied to a mixture of gas and finely divided solid, the solid tends to separate by reason of its higher specific gravity. This, in fact, is the principle of the well-known cyclone dust-collector. Any mixing device that produces such agitation of the dust and air as to give a centrifugal effect will tend to separate, not mix, the air and the dust.

The importance of mixing the coal-dust and air intimately cannot be exaggerated. The rapidity of combustion is a direct measure of the intimacy of the mixture. This is well illustrated by comparing the ordinary gas-flame with the flame obtained in the Bone combustion system, which consists in forcing the proper proportion of air and gas through a diaphragm having numerous interstices. When this mixture is ignited on the other side of the diaphragm, it produces a film of flame.

The poorer the mixing, the longer the flame. The flame simply outlines the area in which combustion is taking place and the length of the flame is a measure of the time element necessary to accomplish combustion. This time element—other conditions being equal—is absolutely a function of the intimacy of mixture, as was noted by Breenridge ten years ago, when in Bulletin No. 325 of the U. S. Geological Survey, he stated:

"The conclusion is reached that the velocity of combustion decreases enormously from the surface of the fire to the rear of the combustion-chamber, where it is relatively very small, the practical application is that little is to be gained by adding further length of smooth combustion-chamber, which would be commercially as

poor an investment of capital, as to add to the length of a Corliss engine-cylinder and stroke; we must resort to thorough mixing."

Just as in the past there has been a remarkable failure to realize the necessity for intimately mixing air and coal-dust, so there has been insufficient consideration of the characteristics of this fuel when burning. Powdered coal has the characteristics of a rich fuel of somewhat higher kindling temperature than producer-gas, natural gas, or fuel-oil. To illustrate the fact that it is a rich fuel, we can compare the available B.t.u. in a cubic foot of a correctly proportioned mixture of powdered coal and air and the available B.t.u. in a cubic foot of correctly proportioned mixture of pure methane and air. Take a Pittsburgh coal (heating value 14,157 B.t.u.) of the following analysis:

	%
Volatile	35.4
Fixed carbon	58.5
Ash	6.1

We find that a cubic foot of a correctly proportioned mixture of coal-dust and air has available 107 B.t.u., while a mixture of pure methane and the proper amount of air has available per cubic foot, 62.3 B.t.u.

The rapidity of combustion and the completeness of combustion of a mixture of coal-dust and air depend upon a number of factors: for example, they are dependent upon the velocity and pressure at which it is passed into the combustion-chamber. If the velocity of the incoming stream of powdered coal and air is above the velocity of flame propagation, combustion will not take place until the mixture has slowed down to a point that it does not exceed the velocity of flame propagation. When powdered coal is fired at high pressure and high velocity, combustion frequently does not begin until a point four to six feet from the mouth of the burner. A similar example is found in the plumber's blow-torch when too much air is used, or in the Bunsen burner when the gas-pressure is too high. High-pressure firing not only slows down combustion, thus increasing the size of the chamber necessary, but has a destructive action on the furnace. It has been well established that high velocities in the combustion-chamber or a blow-torch effect due to firing at high pressure (whether oil or gas be used as a fuel) are always destructive of the brickwork. This action is increased in high-pressure firing of powdered coal, since, in addition to the erosional effect of gases at high temperature traveling at high velocity, there is a fluxing action by the melted ash. Furthermore, the slagged ash will be carried along mechanically, leading to further furnace troubles. In one case this resulted in a deposit of slag on the mud-drum of a vertical waste-heat boiler at the end of a long reverberatory furnace. Slowing the velocity not only hastens combustion, but makes it possible to eliminate much of the slag. When the velocity is low the coalesced particles of slagged ash are either larger than will be carried by the velocity of the gas or this condition is so nearly approached that a slight change in direction of the flame will result in dropping out the slag. Thus, in addition to being correct com-

bustion and necessary in order to avoid excessive furnace-maintenance costs, low-velocity combustion, by a slight change in flame direction, permits the dropping out of a large quantity of the slagged ash in the early part of combustion, where it can be removed and will not interfere seriously with efficient metallurgical operations.

The velocity of combustion is not only dependent upon the fineness of the particles of coal, the intimacy of the mixture, and the velocity of the stream of combustible and air, but is affected by the temperature of the combustion-chamber. The kindling temperature of a mixture of powdered coal and air is higher than that of either oil or gas; consequently for successful and complete combustion, it is necessary that the combustion-chamber be maintained above a certain minimum temperature and that the combustion be practically completed before the products of combustion pass over the heat-absorbing surface. Just as you can extinguish a gas flame by passing over it a piece of wire-gauze, so the effect of a chilling surface will be even more marked with this combustible material than with burning gas, since the particle of coal is infinitely larger than a molecule of gas and the kindling temperature is also higher. This has a direct application to the successful firing of locomotive boilers, water-tube boilers, and return-tubular boilers. If the combustion of powdered coal be not sufficiently developed before the flame enters the tubes of the locomotive boiler, combustion will be checked and coked coal settle out in the tubes. If, on the other hand, combustion be sufficiently developed before the flame is brought in contact with the heat-absorbing surface, complete combustion and high efficiency are obtained.

A study of the flame developed at a low pressure by an intimate mixture of coal-dust and air shows that combustion is extremely rapid. In a copper-reverberatory furnace at Florence, Colorado, where this type of combustion is used, coal burned at the rate of approximately one ton an hour develops a flame that vanishes within six feet of the burner, combustion being complete at that point. Let us translate this into terms of natural gas, in which case the fuel consumption would be approximately 26,000 cu. ft. per hour or 433 cu. ft. per minute. You can picture to yourself this quantity of gas being burned at low pressure and developing a flame only six feet long. Samples of gas taken in the flame show a content of CO_2 as high as 16% only five feet from the mouth of the burner. This will give an example of the rapidity with which combustion can be obtained and the possibilities of shortening the flame. With proper equipment is is equally practicable to lengthen the flame until it will spindle out a distance as great as 100 or 120 ft. However, with an intimate mixture under control, this must be done by supplying insufficient air. Under such conditions combustion is incomplete and the flame spindles out because combustion continues to develop throughout the length of the furnace as air-leakage supplies additional oxygen. This is proof of the statement that the length of flame is an actual measure

of efficiency of mixing and the adjustment of the fuel-air ratio.

Thus, it is seen that we have changed entirely the characteristics of coal as commonly known. Powdered coal is a fuel of extreme flexibility, in that the amount burned can be varied within wide limits. It is a fuel that develops a flame whose length can be adjusted. The character of the flame can be altered to suit the metallurgical operation. In short, the basic fuel, coal, has acquired the characteristics of oil or gas, but with better and closer control. Furthermore, the possibilities of this fuel are not only capable of realization, but are actually being utilized in commercial practice today. To the flame characteristics of a rich fuel, developing a flame like oil or gas, is added a degree of control not yet obtainable in burning either oil or gas. This statement is made advisedly. The possibilities of such combustion for the improvement of processes, for fuel economy, for increasing output, through its ease of control and elimination of heavy labor, are realized by few. Owing to the attitude of labor and the scarcity of skilled operatives, it is far more difficult than ever before to secure high efficiency and good operation in hand-firing, stoker-firing, or in producers, in short, whenever such efficiency depends upon constant watchfulness and hot, heavy, disagreeable work. For these conditions powdered coal substitutes an ease of control such that the equipment can be handled by an old man or a boy, while it is so simple that a man of ordinary intelligence can soon be taught all that is necessary for good efficiency in operation. The possibilities of such control in the place of present-day combustion methods, which permit high efficiency only by the most strenuous effort, through substituting for these a type of combustion whereby high efficiency is easily obtained, are certainly of great importance to us at the present time.

To those who are in touch with many diversified chemical industries, the possibility of maintaining and regulating heating conditions that are oxidizing, reducing, or neutral at will, conditions that once adjusted will remain constant—barring mechanical or electrical interruptions—will undoubtedly suggest many new economies and betterments.

THUONUM, according to R. B. Moore of the Bureau of Mines, is not in large demand at the present time. No domestic market exists, owing to the fact that the grade of the material so far discovered in this country does not hold up to the higher average of the Brazilian and Indian output. The South American product containing $6\frac{1}{2}\%$ monazite, is worth about \$300 per ton. The only purchasers in this country are the Welsbach Co., Gloucester City, New Jersey, the Lindsay Light Co., of Chicago, and the Block Co. of the same place.

SULPHUR in Germany is being obtained at the present time almost exclusively by the reduction of gypsum. It is reported that deposits of anhydrite are similarly being utilized.

Electric Welding Tests for Ship Construction

Final arrangements have been made for a series of extensive tests covering the use of electric welding in ship construction at the works of the Federal Shipbuilding Corporation, Kearny, near Newark, New Jersey. As a basis for the general adoption of spot and arc welding in the construction of steel vessels, a typical 40-ft. hull, exactly similar to those now being built at the plant, will be assembled by the new method. Following initial investigations, it is pointed out that this process gives evidence of effecting great economy in time and money over the methods now regularly used, and moreover, affords particular flexibility for adoption in the building of the heavy type of steel ships. It is estimated that it will be possible to save a month's time in the construction of a 10,000-ton vessel, as well as about \$40 per ton in the cost of the steel structure, making a total saving of approximately \$100,000 on a ship of this size. The factors considered in these estimates include the elimination or the minimizing of the work of the template-maker and marker, fitters and bolters, the punching of holes and, where the rolling-mill and fabricating shop are not in the same yard, the transportation of material between the two plants.

In carrying out these tests, it is proposed to make the initial assembling of the hull by spot welding, bringing the work to a point where the vessel is sufficiently strong to hold its shape. The subsequent operations will be handled by the arc-welding process, making the seams of adequate strength and water-tight. On the test hull, three-quarters of the structure will be welded and one-quarter riveted to allow a basis for comparison in placing the work under tests for pressure and strength. The primary test will consist of filling the hull with water and shifting the points of support, followed by bumping with rams, and subjecting it to other abuses, to determine the capability of the finished hull. The tests will be conducted by Arthur J. Mason of the New York office of the U. S. Shipping Board, who, in a preliminary report to Charles Piez, vice-president of the Emergency Fleet Corporation, points out that only about one-fifth of the men working on a steel hull under the present system of construction are riveters, the other four-fifths being engaged in flogging and pulling the frame together by bolts. The spot weld, it is stated, will prove a much more vigorous agency for accomplishing this purpose. The problem of fitting in place the parts of a hull are almost wholly those arising from the necessity of making a number of small holes in a plate by one man at a time, and fitting a number of small holes made by another man at another time and place. By the welding process, all holes are left out of the material, all the parts fit, and creeping and kindred difficulties disappear.

QUOTATIONS on sulphuric acid at Baltimore at the end of May were \$25 per ton for 60° B., and \$40 for 66°. No free offerings of acid are being made by manufacturers.

Reducing Zinc Loss in Brass-Making

The Bureau of Mines has developed a type of electric melting-furnace that may revolutionize the melting of brass. Patents on this furnace, which is known as the rocking electric furnace, have been taken out by the Bureau and assigned to the Secretary of the Interior as trustee. Free licenses to operate these furnaces under patents can be obtained by applying to the Director of the Bureau of Mines. This furnace is the result of five years experimentation by H. W. Gillett, chemist of the Bureau of Mines, in co-operation with the laboratory of Cornell University, the American Institute of Metals, and numerous manufacturers of brass. Brass is usually made in costly crucibles of imported clay and graphite. Since the War began it has been impossible to obtain these materials in sufficient abundance, and manufacturers have had to use crucibles of poorer quality, and at a larger cost. With the huge tonnage of brass needed for war purposes, such as shells for cartridges, manufacturers have been anxious to obtain a solution of the problem. The Bureau states that electric furnaces will largely replace crucible furnaces and that there will be a development comparable to that seen in the steel industry in the last few years. The electric furnace will greatly decrease the loss of zinc in the process of brass-making. Zinc boils at a much lower temperature than copper, and there have consequently been large losses in the open-crucible furnace through volatilization. The electric furnace is closed and these losses are avoided. It is estimated that the unnecessary loss in brass-making is more than \$3,000,000 per year in normal times and perhaps at the rate of \$10,000,000 per year at present. Another claim made for the electric furnace is that the working conditions for the men are more healthful. The Michigan Smelting & Refining Co., Detroit, Michigan, has one of these furnaces in operation and four more under construction, while the C. B. Bohn Foundry Co., also of Detroit, is building two furnaces.

NITROGEN fixation by the Reid process, which has been favorably reported upon by the Government, is accomplished by producing carbide through first coking a mixture of ground coal and lime, and reducing the lime-coke thus formed in a type of electric furnace that permits of the use of 'off-peak' power. Such power can be had at low rates. The Reid process nitrifies the carbide at a lower temperature than the cyanamid method, and by the use of a catalyzer reduces the lime required for nitrification. The cyanamid produced gives off its fixed nitrogen in the form of ammonia on treating it with waste or moist steam.

GRAPHITE crucible manufacturers are said to require 30,000 tons of graphite this year, and if transportation can be had a market exists for about 8000 tons more flake graphite than now is in sight. According to the Department of Commerce the imports of graphite in 1917 amounted to 42,609 short tons, valued at \$8,961,988.

Hand-Sorting of Mill-Feed

By R. S. HANDY

*Does hand-sorting of mill-feed pay? The fact that the practice is so general would seem to indicate that there must be good reasons for it; yet, to my mind, the advantage in many cases is doubtful enough to invite a thorough discussion, in an effort to determine under what conditions hand-sorting does pay.

A typical sorting-plant in the Coeur d'Alene region handles about 800 tons of mine-run ore per day. The material is run over a grizzly with a 4-in. opening; the oversize is crushed to 4-in. size and joins the undersize, and the whole product is washed and screened on trommels with 1½-in. openings. The oversize from these trommels is spread on a belt and the waste and first-class ore are sorted out by hand, the residue being further crushed,

and the power consumed are not greatly different from those required in a sorting-plant of the same capacity, and the normal cost of thus preparing the feed for milling is under 3c. per ton of mine-product. The relative cheapness of this method as against hand-sorting is thus clearly established, the saving being about 13c. per ton. If there is any virtue in hand-sorting, then, it must lie in the metallurgical results achieved.

Possibly the favor that hand-sorting has found is due to a misconception as to what happens to the clean shipping ore if it is sent to the mill. If a mill makes, say,

FIG. 1.

to pass, together with the trommel undersize, into the mill-feed bins.

About 50 tons of shipping ore and 150 tons of waste are sorted out per day, leaving about 600 tons of mill-feed. To sort out this material requires 20 sorters with five bosses and repair-men. The normal cost of hand-sorting is about 16c. per ton of run-of-mine, or 65c. per ton of material sorted. I believe that straight crushing and milling of the run-of-mine, in this case, is not only cheaper, but is metallurgically more effective than hand-sorting followed by milling of the residue.

At one of the Bunker Hill rock-houses, 1250 tons of run-of-mine are reduced to pass 30-mm., or about 1½-in. opening in six hours, requiring five men. The equipment

FIG. 2.

an 80% recovery on its feed, the advocate of hand-sorting may assume that if the hand-sorted product be sent to the mill, 20% of the valuable metals will be lost. This, I believe, is a false assumption. There is no ore of shipping grade getting past the first two cups of the jigs in the Bunker Hill mill, down to at least 7 mm. in size, and very little gets into the middlings in the sizes below 7 mm. Of course, none gets into the tailings. The only loss, then, in milling the hand-sorted product must be the losses due to sliming in the crushing operation and the slime lost on account of attrition of the soft galena in the jig-beds. Crushing through 1½-in., in our experi-

*Trans. A. I. M. E., to be read at the Colorado meeting, September 1918.

ence, produces less than 2% of material below 40-mesh and the saving on this product nowadays is practically the same as on the coarser material.

I have tested our jigs time and again for slime losses, and have found that the slime in the tailings of all the jigs down to 7 mm. size, including those from the re-concentrating jigs, does not exceed 0.1%, by weight, of the tailings. This slime assays about the same as the mill-feed. Attributing the whole of this slime loss to the 50 tons of hand-sorted ore in the sorting-plant mentioned would account for the loss of about 50 lb. of lead per day, against which is the cost of \$30 or \$40 per day for sorting.

Our bull-jigs, treating material between $1\frac{1}{4}$ and $1\frac{1}{2}$ in., make no shipping product—only middling, which is crushed through rolls and re-concentrated, and tailing. Therefore, there are no smooth, worn 'marbles' of galena in the beds of our bull-jigs, such as occur when jigs are forced to produce a higher-grade product than the conditions warrant. For example, if we try to make a shipping product in our bull-jigs, about the best grade we can get is 55% lead, and under these conditions there is considerable wear of the soft material on the jig-beds. By taking off a middling product assaying about 25% lead, and crushing and re-jigging this, we can easily produce a concentrate in the re-concentrating jigs assaying 65% lead with very little wear on the bed.

Considering the slight mechanical losses that occur in milling the hand-sorted ore, there is little to be said in favor of hand-sorting from this standpoint.

If there is no advantage in sorting a shipping product, there must be less advantage in sorting waste, when the cost is 50 or 60c. per ton of waste rejected. Each of our bull-jigs will treat 150 tons of feed per 24 hours and throw off 90 tons of tailing assaying less than 0.4% lead. I am satisfied that a jig handling larger sizes and designed primarily to discard tailing could throw off waste of lower grade and do it much cheaper than any method of hand-sorting in use.

There is an economical advantage in the milling of ore as against hand-sorting. This is in the grading of the products, as is illustrated in the accompanying chart, Fig. 1. Beginning at the left, a curve is drawn showing the net smelter-value of mill-product derived from conditions shown in the other curves. The top scale indicates the tons of product shipped, and the scales on the left and right indicate the units on the curves. For example, if 1400 tons of product (or the mill-feed, assaying 10% lead and 4 oz. silver per ton) are shipped to the smelter under the conditions stated in the note, the recovery of lead and silver is 100% and the net smelter-value is \$2800. If nothing but the clean galena is shipped, about 50 tons can be produced, assaying 86% lead and 26 oz. of silver. The recovery of lead would be about 30% and the net smelter-value of the product would be \$4500. If a concentrate assaying 33% lead were produced, a recovery of 95% of the lead and 84% of the silver would have to be obtained to get the same net smelter-value in the product as that recovered when the grade of the product is 60% lead and the recovery 85% of the lead and 75% of the silver. The latter condition

seems to be the most economical under the conditions stated. That is, there seems to be a definite economic peak in the milling of ores where the various factors of recovery, grade, and cost combine to give a maximum net value, or money return, to the operator.

When hand-sorting was practised at the Bunker Hill plant, it was not practicable to sort out a product containing over 45% lead, and I understand the average grade was less than that. In order to estimate the possibilities of hand-sorting at the Bunker Hill plant under the conditions existing at the sorting plant first mentioned, I have used 45% lead and 16 oz. of silver for the hand-sorted product and the economic relationships in the various treatments possible for this product have been indicated graphically in Fig. 2. This is based on a production of 90 tons per day of hand-sorted shipping product, which would be the Bunker Hill production under the conditions stated. The net smelter-value of these 90 tons, under the conditions stated on the note in the chart, would be \$3870 and the recovery of the metals, from a milling standpoint, would be 100%. If this material were milled and a concentrate produced containing 84% lead and 29.8 oz. of silver, 43.5 tons of such concentrate would have to be produced to equal the net smelter-value of the original ore. This would mean a recovery of the metals of 90% and the discarding of 46.5 tons of tailing assaying 8.5% lead and 3.1 oz. of silver. If the grade of the concentrate produced is 60% lead and 21 oz. of silver per ton, the recovery is about 94% and 26.5 tons of tailing is produced assaying the same as before. The production of a concentrate, from the treatment of this material, assaying 60 or even 70% lead would be an easy thing to do, but I think it would not be necessary to discard a tailing assaying over 8% lead in producing this concentrate. In fact, it could probably be done with a tailing running less than 2% lead, in which event the economic advantage over hand-sorting would be very large.

The crux of the whole matter is, "What can you do with the hand-sorted product in the mill;" and not, "What does the mill do on the feed it is getting?" The only sure test is to run the mill on a hand-sorted product long enough to determine what grade of concentrate and of tailing can be achieved. I am sure a test of this kind would surprise many of the advocates of hand-sorting by demonstrating the enormous economic advantage to be gained by the opposite method of treatment.

ELECTRO-CHEMICAL separation of tin from other metals is proposed by Leon-Charles Delahaye in a French patent, No. 484,148, issued September 7, 1917. The tin is deposited from an electrolyte consisting of NaPO_3 , Na_2SO_4 , NaCl , Na_2CO_3 , preferably in the proportions for 100 litres of H_2O , of 12, 10, 10, and 2 kg., respectively, using crystallized Na_2SO_4 and dry Na_2CO_3 . The current density should be about 150 amp. per sq. m. of the cathode, and the voltage should vary, during the electrolysis, from 3 at first to 4 to 5 volts toward the last. The best results are obtained at a temperature of about 95° Centigrade.

The Geology and Ore Deposits of Ely, Nevada

By ARTHUR C. SPENCER. Précis by JOHN B. HASTINGS

***STRUCTURAL GEOLOGY.** The Ely quadrangle is in the Great Basin area of eastern Nevada, which is characterized generally by long north and south mountain ranges and intervening valleys, each five to ten miles wide, and as much as 140 miles long. These ranges are late Tertiary areas of elevation and depression.

The district may be regarded as a shallow north-south syncline, with rude flanking arches, disturbed by unsystematic dislocation from early to late geologic time, contrasting with the orderly north-south faults determining the larger topographic structure. The syncline is something like the depression made by the body in a bed and the higher sides and presumably on the edges of the bed-faults marking the eastern and western scarps of the range. The exposed sedimentaries forming the area are: Carboniferous, Pennsylvanian, the Areturus limestone, exposed 400 ft., Ely limestone 2500 ft.; Mississippian, the Chainman shale 250 ft., Joanna limestone 100-400, Pilot shale 200; Devonian, the Nevada limestone 4000; Ordovician, the Eureka quartzite 150 ft., and the Pogonip limestone, exposed 1400 ft. They have been greatly disturbed by faulting, and to a less extent by folding, so their areal distribution is very irregular. Since the close of the Carboniferous it has been a land area.

MONZONITE INTRUSION. The six uppermost of the eight formations in one place or another have been invaded by monzonite porphyry. The intrusion of the monzonite, one-half to one mile wide by seven miles long, from east to west across the syncline, occurred at the close of the Jurassic, or post-Jurassic, and though the rock may differ in appearance and composition, it is thought, from the latest mine development, that it all belongs to a single igneous epoch.

ALTERATION OF THE ROCKS. The heat and the emanations from the intrusions altered the adjacent sedimentaries for a few hundred to 2500 ft. from the contact, the effect decreasing with remoteness. Finally, after cooling and crystallization, the monzonite was itself metamorphosed and mineralized, by continued ascent of solutions, especially along a wide middle band. These solutions, from first to last, introduced silica, sulphur, iron, and potassium, also copper, lead, zinc, gold, and silver, more of the latter minerals into the porphyry in the final stages than previously into the sedimentaries. Carbon di-oxide is believed to have been plentifully present, but if the solutions were originally acid through attacking the rocks they would become alkaline or neutral and then deposition of the metallic minerals would take place.

Alteration of the limestone consisted principally of one simple crystallization and the loss of carbonaceous blue and black coloring, making a fine-grained marble; of metasomatic replacement by quartz and sometimes chaledony, yielding jasperoid, presenting prominent rusty outcrops; of development of lime-bearing silicate minerals, commonly garnet and tremolite, but also white and brown mica, pyroxene, epidote, and scapolite; and of the formation of pyrite and pyrite-magnetite bodies, with some pyrrhotite, chalcopyrite, sphalerite, galena, molybdenite, and hematite. The altered limestone, shale, and porphyry are all impregnated with 2 to 10% pyrite, and with chalcopyrite from nearly nothing upward. The shale altered to pyritiferous hornstone. Microscopically they show felty or finely granular wollastonite, epidote, calcite, pyrite, and magnetite. Sometimes pyrite was introduced synchronously with pyritization of the monzonite.

In the monzonite alteration, much of the rock was greatly seamed by quartz and sulphide-bearing veinlets, or by films of pyrite; but other portions are quite or nearly free from such filling, yet both kinds of material are thoroughly altered in bulk, and are generally highly impregnated with pyrite, accompanied by chalcopyrite. The solutions that caused the alteration penetrated so deeply that after being metamorphosed large masses of porphyry, essentially lacking in fracture-filling, carried chalcopyrite in such quantities that a slight enrichment has been adequate for their conversion into commercial ores. However, the content of chalcopyrite in the metamorphosed porphyry is ordinarily higher where the rock was considerably crushed and filled with quartz prior to its complete alteration than when the only alterations were those due to permeation into the rock. Perhaps also the rock-minerals have undergone somewhat more complete alterations where vein-stuff occurs than elsewhere. All things considered, the order of the mineralization seems to have been: (1) permeation of the rock by solutions capable of producing alteration; (2) formation of veinlets, usually of quartz, or of quartz with a little orthoclase and biotite, carrying distributed pyrite and chalcopyrite. Some of the veinlets carry a medial film of pyrite; (3) the deposition of pyrite films in joint-fractures. These three sorts of mineralization may be observed together in material from the open pits of the Nevada Consolidated Co., from the Butte-Ely shaft, and from the porphyry mine of the Giroux Co. In other material from the same localities, and from the Veteran mine, the first and second alterations are noted without the third; in material from Weary Flat and from the Eureka shaft on the Ely Central property, the second

and third alterations are most prominent, and in material from the McDonald-Ely shafts in the eastern part of the district alterations which seem to be related to the third class are mainly in evidence. The alterations of the porphyry, which are of the greatest interest in the formation of copper ores of the disseminated type, are those that have been produced through the permeation of the rock-mass by magmatic solutions. These alterations comprise, in different stages, the progressive destruction of hornblende, of plagioclase, and of magnetite, and the formation in their stead of mica, including the white variety of felty habit commonly called sericite, and a brown variety allied to biotite, the deposition of pyrite and chalcopyrite, and also of calcite. Pyrite and chalcopyrite occur mainly in the altered ground-mass, but are also found in the sericitic aggregates and rarely in the large orthoclase crystals. The ground-mass of the thoroughly altered porphyry has a granulated appearance quite distinct from that of the normal rock. In extreme alteration the rock is a felt of sericite flecked with grains of sulphide and of quartz.

LATE VULCANISM. In the Tertiary, probably in Pliocene time, vulcanism was again active in north-east Nevada, and though little has withstood erosion, tuffs and rhyolite probably covered nearly the whole Ely quadrangle. White to gray fragmentary tuffs, evidently from explosive eruptions, occur in the rhyolite area north of Lane valley, between the upper part of Robinson canyon and Lyon spring; they have been quarried for building purposes one-half mile west of Keystone, where the railroad leaves the canyon, and between Ruth village and Copper Flat. Black obsidian overlies the tuffs north of Lane valley and near the railroad spur west of Star Pointer. Lastly older and younger rhyolites were extruded, being purple or red massive rocks with grains of black quartz and sanadine phenocrysts, west of Liberty pit, between Copper Flat and Star Pointer, and north of Lane valley, while lighter colored, platy, fluidal rocks, are also found north of Lane valley and on the north side of Keystone hill. The former older flows are known, which are as much as 465 ft. thick, as demonstrated in the Eureka shaft of the Ely Central, while the later flows may be 300 feet.

QUATERNARY CLIMATIC CONDITIONS. The Quaternary was marked by alternating wet and dry climates over Nevada, Utah, and Idaho, evidenced by the formation of all of the great geologic lakes, of which Salt Lake is now a diminutive remnant. Once it was 800 ft. deeper than at present, and extended to within 30 miles of Ely. This prehistoric enlargement is designated Lake Bonneville. The dry and wet changes are: (1) pre-Lake Bonneville epoch, characterized by an arid climate, and marked by an accumulation of alluvial deposits, which flank the mountain masses; (2) first flooding of the basin as a result of increased humidity; (3) dessication from aridity of climate; (4) second flooding, indicating humidity; (5) present epoch of aridity. During the first alluvial cone was dropped at the mouth of Steptoe creek,

there being insufficient water to carry it farther; in the second the creek was larger and, cutting through the cone, distributed its load in the lower valley; the third was not quite so dry as the first, and its cone, more widely spread, was formed farther out in the valley, and has since been obliterated by erosion and further deposition. However, traces of changes corresponding to the third, fourth, and fifth are not quite definite. Steptoe cone is terraced 150 to 40 ft. above the present flood-plain, the upper bench probably resulting from the lateral erosion of a perennial stream during the second, and the lower bench the same during the fourth and fifth stages. The present dry climate is reflected by the clogged condition of Robinson valley below Keystone, where loose debris fills the channel to depths of 30 to 80 ft., and also in the conical piles of alluvium at the mouth of steep side gulches.

ORIGIN OF THE CHALCOOCITE OR SECONDARY ENRICHMENT. Metallic sulphides are easily decomposed by oxygenated waters, but the amount of oxygen the Ely mine water could carry downward would not be sufficient during the age of the earth to affect the amount of oxidation that has taken place. As this really has transpired other explanations must be sought. The first step is the easy circulation of air through the porous capping, continually replacing oxygen depleted from the descending percolating waters. The incomplete oxidation thus effected is indicated by Gottschalk and Buehler, changing the pyrite into ferrous sulphate, sulphur, and sulphur dioxide. Oxidation by free oxygen takes place as follows:

With water and a higher oxidation into ferric sulphate, with generation of sulphuric acid, the reactions would be:

Then, from (1) and (2):

For chalcopyrite, analagous to (1) and (2):

Part of the ferric sulphate formed decomposes to basic iron sulphates and hydrated iron oxide.

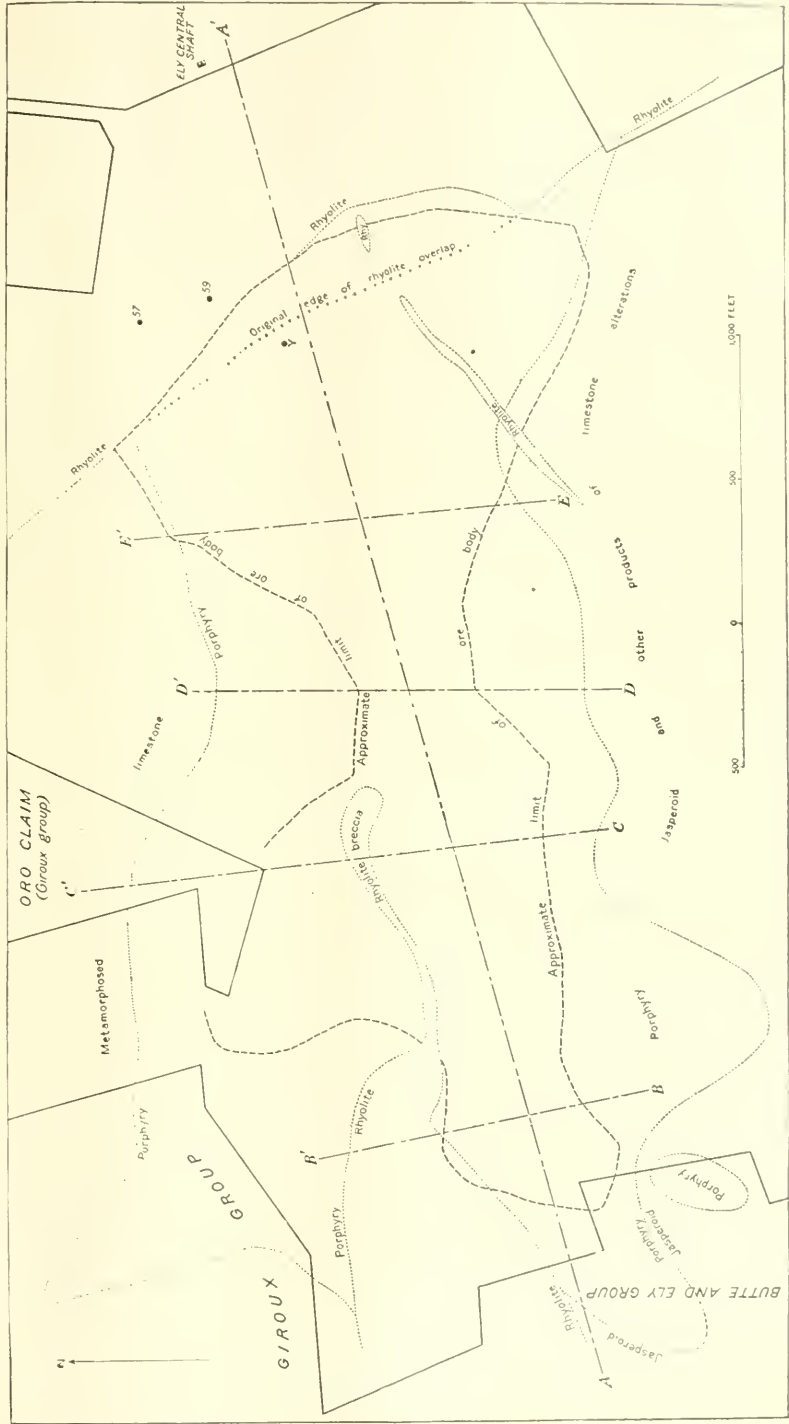

and part may descend to attack pyrite, chalcopyrite, and chalcocite.

The descending sulphuric acid and ferric sulphate solutions quickly encounter chalcocite, and if free oxygen remains chalcocite is decomposed into cupric sulphate.

It may be assumed this uses the last of the free oxygen,

MAP SHOWING PLAN OF ORE BODY AND AREAL EXTENT OF PORPHYRY IN COPPER FLAT-LIBERTY MINE.
Data in part from annual report of Nevada Consolidated Copper Co. for 1913. A-A', etc., Lines of sections shown in Plate XII.

but ferric and cupric sulphates remain, both capable of oxidizing sulphides; the ferric being more easily reduced might almost all become ferrous before the cupric became an oxidizing agent.

OXIDATION BY FERRIC SULPHATE. Where chalcocite and other sulphides occur together, especially as at Ely, where chalcocite coats pyrite and chalcopyrite, chalcocite is the first mineral attacked, and protects the others. Vogt gives an equation for the change of ferric sulphate and chalcocite into ferrous and cupric sulphates:

Sulphur might react with more ferric sulphate and form sulphur dioxide (7), and dioxide with more ferric and produce sulphuric acid (8), leading to an equation of Weed's:

(5a) may be regarded as summarizing the following steps in oxidation:

Ferric sulphate may be considered as acting on pyrite about as follows (6), (7), and (8) leading up to (9), and (9) comparable to (1).

For chalcopyrite an expression similar to (9) is:

After allowing for great irregularities in the under surface of the oxidized capping in contact with the subjacent ore due to fractures in the latter, in which occasionally the chalcocite appears unattacked, the decomposing power of the downward moving waters, as dependent on free oxygen, appears generally to be spent in a shell of, say, 3 ft. thick, though impoverishment may continue considerably deeper through ferric sulphate reacting on chalcocite, as in (5) and (5a).

Therefore it may be concluded: (1) so long as descending surface waters can acquire free oxygen, or contain ferric sulphate, they will strongly decompose metallic sulphides; (2) where chalcocite, pyrite, and chalcopyrite are present, chalcocite will be largely, perhaps fully, decomposed before the others are attacked; (3) the decomposition of chalcocite, chalcopyrite, and pyrite reduces the ferric salts; (4) their decomposition tends to produce sulphuric acid; (5) decomposition of chalcocite and chalcopyrite furnish cupric sulphate.

OXIDATION BY CUPRIC SULPHATE. The descending waters do not now contain free oxygen and very little

ferric sulphate, but they carry ferrous and cupric sulphates and sulphuric acid. The cupric sulphate survives because at ordinary temperatures, and in acid solution, it is less readily reduced than ferrous sulphate. Dilute sulphuric acid at ordinary temperatures without oxygen does not decompose chalcocite, and probably does not attack chalcopyrite or pyrite. Cupric sulphate, at high temperatures, reacts with chalcocite to form covellite and cuprous sulphate, and the former, on cooling, decomposes, precipitating metallic copper. Cupric sulphate attacks chalcopyrite and pyrite at ordinary temperature, forming ferrous sulphate and sulphuric acid, and a copper sulphide is deposited.

The suggested equations are: pyrite to chalcocite through cupric sulphate, as:

Next, pyrite to covellite:

And pyrite to chalcopyrite:

These complete reactions may require steps through minerals intermediate between pyrite and chalcopyrite and between chalcopyrite and chalcocite.

A summary of equations, from chalcopyrite to chalcocite and to covellite, analogous to (10) and (11), is:

Detailed examinations of polished surfaces and thin sections show that in the Ely mines, though chalcocite replaces pyrite, if chalcopyrite is present it is the mineral mostly affected.

GEOLOGIC AGE OF THE CHALCOCITE ENRICHMENT. The transfer of copper from the upper to the lower portions of the porphyry, as described, has kept pace with the erosion of hundreds, perhaps thousands, of feet of the intrusion, but probably the erupted Pliocene rhyolites covered the ore-belt, making a long interval of abeyance during its removal, and there has been little erosion since the beginning of the pre-Lake Bonneville epoch; therefore it is judged that practically all the secondary copper of the present enriched orebodies is due to conditions during late Pliocene time, but re-distribution of the metal has been going on since then, gradually lowering the top of the orebodies.

CHARACTER AND EXTENT OF THE ORE DEPOSITS. The productive ore is a chalcocite enrichment of pyrite monzonite porphyry, bringing the original 0.5% copper in the chalcopyrite as high as from 1 to 3%. The orebodies are

LONGITUDINAL AND CROSS SECTIONS OF COPPER FLAT-LIBERTY MINE, SHOWING ORE BODY AND EXCAVATIONS.
For position of sections see Plate XI. Data mainly from annual report of Nevada Consolidated Copper Co. for 1917.

irregular layers that lie beneath highly oxidized products of weathering and rest on entirely unweathered material, similar to the ore but without chalcocite. They occur medially along an east-west monzonite intrusion seven miles long, and one-half to one mile wide. The ore is a uniform light gray rock, from innumerable black specks of chalcocite, or of chalcopyrite and pyrite coated with chalcocite, but mainly the former, and its coverings are very much heavier. The white portion is quartz, orthoclase, and sericite; fresh yellow pyrite also occurs. Most of the pyrite that is coated with chalcocite is less than half a millimetre in diameter, while that not coated is mainly large and in bunches and seams. The only non-metallic mineral developed during the enrichment is kaolinite from orthoclase, and this is rare. An unusual appearance is black reticulating films of pyrite crushed by movement into dust, and coated with chalcocite.

In 1913, 80,000,000 tons of copper ore, with a small gold and silver content, including ore already mined, had been proved in this area. The 10th Annual Report of the Nevada Consolidated Copper Co. states that by December 31, 1916, they had developed in their own ground, 89,766,723 tons containing 1.6% copper, of which 21,773,606 tons, containing 1.67% copper, had been milled. To the first figure should be added 800,000 tons, on account of the Veteran mine. The latest tonnage developments are below the zone of distinct secondary enrichment, and, as a result of investigation, are thought to be primary.

Space prevents a description of minor ore occurrences in the jasperoid and shale, and in off-shoots from the main body in the porphyry. It is intimated that there is a definite east to west line of fracturing of the monzonite, which allowed the ascension of mineral-bearing solutions from depth, greater in volume than those contained in the intrusion itself.

REVIEWER'S REMARKS. It is hardly probable that the Nevada Consolidated ground covers more than half the possibilities of the district. The geologic and topographic surveys were finished in 1910, and the report issued in November 1917. Is there room here for criticism? The Chainman vein was a continuous channel in the limestone, as developed say 1000 ft. long, 20 ft. wide, and sometimes 200 ft. deep, and uniform in appearance. It was a mass of rounded boulders and interstitial filling of silica, probably other non-metallics, magnetite, some lead carbonate, all deep red from abundant limonite. The persistence of the rounded boulders, from the size of a marble to 6 ft. diam., passing through the Chainman into the Joanna ground attracted everybody's interest; it was suggested that the creek once followed the lead, it being perfectly understood that the erosion was chemical and not by attrition. The best ore in large quantity averaged \$4.50 gold, but small areas were richer. Above the lime there were also areas of shale metasomatically replaced by quartz; the bulk stoped probably averaged higher than \$10. At the time of my examination in 1894 there was a remnant left in the bottom of an old stope. The metasomatism was interesting in its delicate complete-

ness; the shale, almost entirely silicified, looked unchanged except for a glisten. The ore left was about 50 ft. long, 8 ft. wide in the centre, 3 ft. at each end, and it assayed \$40 in gold, but it continued only about 10 ft. deeper, terminating without faulting in a conchoidal fashion against the big low-grade vein. The best ore was thus silicified shale, presumably Chainman shale. Possibly similar bodies yet may be found below the Joanna limestone in the Pilot shale. From here I was called to Monkey Wrench (afterward named Delamar, Nevada), and there I saw another phase of metasomatic replacement of quartzite by silica. One thousand tons had been shipped from the Discovery stope to Salt Lake, yielding \$100,000. While sorting to this grade the owners had collected a few pounds of the best specimens. There was nothing to show its richness except spots in the quartzite made by the new silica, looking as if it had been wet with water.

It is always interesting to find important work like this referring geologically to the solid foundations of the 40th Parallel-Survey carried across the West by James D. and Arnold Hague, and S. F. Emmons, with Clarence King as their chief, whose charm of character seems depicted in the massive yet graceful tomes and atlas of the report. I asked Mr. Emmons how they managed to do it, just out of college, when there was not too much known of geology by anybody. He said, "We learned as we went; we taught ourselves by studying the structures."

Possibly some who may read this paper may not be familiar with Salt Lake and the history of the former Lake Bonneville. Should they ride from Ogden to Salt Lake City, they will easily note terraces along the hillsides denoting levels of the ancient lake 400 and 800 ft. above the present one. Before the Bonneville monograph was published I went with others over some of the remains of the old lake from Bear River, Idaho, southward, with G. K. Gilbert. He took us up the steep hillsides 400 ft. above Salt Lake, to show scarps in the terraced-gravels marking displacements by recent faults, assuring us that the upper bench which looked so near was really 400 ft. higher, as we could easily verify by following him there, but all were willing to take his word. Going over the immense bars formed by the old lake, and replying to flattering comments on his perspicuity, Mr. Gilbert laughingly protested, "Just a longshoreman; you don't need to be much of a geologist."

Monzonite is defined in the report, with reference to the feldspars, as a rock with equal amounts of orthoclase and plagioclase. Thus simplified it might be distinguished from granite, gabbro, and other rocks in the field; in fact granite is becoming scarce. Orthoclase is sometimes pinkish, but more often is only opaque as compared with plagioclase, and, on the latter, fine lines of multiple twinning may usually be detected.

AN INTERFEROMETER is an instrument that makes use of the optical properties of gases, and is suitable for analyzing a binary gas mixture.

The application is duly published in the government bulletin, and the statements are approved and verified by the engineers of the Department of Mines. After approval by the engineers the Government must grant the concession within 30 days.

Only after the granting of the concession can mining operations begin, and then only subject to the rules and regulations of the Government, as follows: 1. Work must be done according to engineering rules and all employers are subject to the police regulations of the district; 2. the operator must be responsible for any damage done to a third party; 3. he is responsible for any damage done by water from the mine; 4. he is responsible for any damage caused by allowing any workings to fill with water; 5. he must begin work on his concession within three months from the date when it was granted; 6. he must work the property continuously, except under rare circumstances; 7. he must keep the mine workings properly timbered and accessible; 8. he must not strip the mine workings so as to render future exploration of the veins difficult; 9. he must not stop work without due notice to the Government, and must leave the mine-workings in a safe condition; 10. he must pay the taxes imposed by law; 11. he must furnish maps and reports annually to the Minister of the Interior; 12. he cannot change technical managers without the permission of the Government; 13. he must provide sanitation for the workmen; 14. guard water for irrigation and not pollute streams; 15. extract only the mineral applied for in the concession; 16. employ no miners under 14 years of age underground; 17. furnish all possible information for mining statistics; 18. assist in making roads, railroads, and transportation systems; and 19. aid in welfare work for the miners.

In passing it should be noted that the law requires that the technical manager of a mining concession shall be a Portuguese. In practice this is merely a formality that provides employment for the engineers of the country. Also it should be observed that the concession once granted may not be transferred without the consent of the Government. If the owner of the concession is not willing to accept the conditions, he must make a declaration to this effect within 15 days, whereupon the Government advertises to see if there are others who desire the concession, and proceeds to sell same at auction. An interesting point of the law is that, while disputes are carried on in the usual courts of law, these courts cannot halt the operation of the property, but must find relief in the seizure of the product of the mine or mill.

The taxes are specifically fixed by the Federal law. The first fixed tax is upon the area of ground and averages about 18c. per acre per annum. The second is a proportional tax of 3% of the gross value of the ore when marketed. The third is a municipal tax not to exceed 10% of 7½% of the ore marketed. The fourth is a local tax which cannot be more than 2% of 7% of the gross value of the ore marketed. A special book of licenses or Government bills-of-lading is required for owners of concessions for removing mineral from a mining property and sending it to the local markets, and one governmental bill-of-lading must accompany each lot of ore whenever it leaves the property. This bill-of-lading must always be with that ore until it is finally consumed or sent out of the country. A special license is also required for exporting the mineral. Infractions of the

laws are punishable by fines and by cancellation of the concessions. It is specifically stated in the law that forfeiture follows when work is not begun within three months from the date of granting the concession; if the owner of the concession does not properly guard the safety of the workmen; if the mining methods are bad so as to endanger the future of the mine; for failure to pay two fines; or for failure to pay taxes for two years; and when the mine is not in constant operation.

Portugal is essentially an agricultural country, and the mines are not extensive or numerous, as compared with the industry in the United States. They will become more important when the laws are amended so as to give greater protection to owners and less authority to government engineers. Wages are low, ranging from 10 cents to \$1 per day. First-class miners get an average of 45c. per day. The development of the country to date indicates that the principal deposits are those of tungsten, copper, chromite, and antimony. Although iron, manganese, zinc, and lead have been found, they give little promise of great economic importance.

Definition of Ship Tonnages

We have been asked to explain the various terms applied to ship tonnages. Briefly they are as follows:

'Register' tonnage is so called because it is recorded in the Register of Merchant Vessels of the United States, and various fees are levied on this tonnage. It is the same as gross tonnage.

'Gross' and 'net' tonnage are based upon a unit of 100 cu. ft. of enclosed space; that is, 100 cu. ft. of enclosed space make one ton. The difference between 'gross' and 'net' tonnage is that 'gross' tonnage is a measure of the entire enclosed space, while 'net' tonnage is a measure of only such space as can be used for carrying cargo.

As the weights of different materials vary, 'gross' and 'net' tonnage are not constant. The 'gross' ton was officially made 100 cu. ft. of enclosed space in England in 1854. The United States adopted this measurement standard in 1864, and now it is universally used.

'Displacement' tonnage is the weight of the water which a ship displaces when floating at rest. The weight of the displaced water is exactly equal to the weight of the body. The naval architect, when designing a boat, must calculate the completed weight of the craft and must proportion and shape the underbody to make the weight of the water displaced at the desired water-line equal to the boat's weight. Every ounce of additional weight must be balanced by displacing an additional weight of water.

The 'dead-weight' capacity tonnage of a vessel is the load it is actually able to carry—or the difference between the weight of the ship with its engines, machinery, passengers, furnishings, and other specified items, and its 'displacement' weight. Fuel, water, crew, and passengers are not deducted in making this calculation. According to 'Motor Boat,' all submarine sinkings are given in gross tons. In the shipping industry a ton is always 2240 pounds.

REVIEW OF MINING

TORONTO, ONTARIO

Mineral Production of the Province for First Quarter of 1918

Returns received by the Ontario Bureau of Mines for the three months ended March 31, are tabulated below. For purposes of comparison the quantities and values are given for the corresponding period in 1917.

Product	Quantity		Value	
	1917	1918	1917	1918
Gold, ounces	127,692	113,387	\$2,601,760	\$2,265,521
Silver, ounces	3,945,957	4,114,856	2,831,873	3,740,843
Cobalt (metallic), pounds	84,710	37,545	78,668	75,625
Cobalt oxide, pounds	83,014	81,760	66,798	130,486
Nickel oxide, pounds	5,495		550	
Nickel (metallic), pounds		44,154		17,662
Other cobalt and nickel compounds, pounds	118,292	143,381	13,695	18,386
*Nickel in matte, tons	10,141	9,677	5,070,410	5,806,200
*Copper in matte, tons	5,063	4,727	2,025,227	1,748,990
Copper ore, tons	1,507		44,097	
Iron ore, tons	23,035	32,530	58,205	127,916
Pig iron, tons	163,020	148,752	2,743,441	3,948,209
Molybdenite, concentrates, lb.	25,073	17,410	32,302	24,548
Lead, pig, pounds	203,046	60,283	27,390	5,066

*Copper in matte was valued at 20c. and nickel at 25c. per pound in 1917. For 1918 the values have been placed at 18½ and 30c. per pound respectively.

Gold.—Production for the period shows only a small decrease, a creditable showing considering the various handicaps under which mines are laboring. The Hollinger had an increase in production which was offset, however, by the closing down of the Dome mill. The Croesus mine in Munro township has suspended work. At Kirkland Lake, a new producer, the Lake Shore, has been added to the list. During the quarter 262,577 tons of ore were treated, yielding 113,387 oz. of gold and 20,221 oz. of silver, compared with 350,916 tons milled during the corresponding period in 1917. Hollinger produced 68,804 oz. and McIntyre 21,461 oz., the next largest producer being the Porcupine V. N. T. The Patricia Syndicate at Boston Creek expected to have its new mill in operation about June 1.

Silver.—Shipments of silver for the first quarter of 1918 show a small increase in quantity and a considerable increase in value. The average New York price for the period was 87.5 cents per fine ounce, or nearly a 12c. increase when compared with this period of last year. Companies shipping 250,000 oz. or over are named in order: Nipissing, Kerr Lake, Mining Corporation of Canada, Buffalo, O'Brien, and Coniagas. The third has been re-modeling its mill in order to treat a large quantity of tailing from the Cobalt Reduction mill. At the McKinley-Darragh a new 200-ton oil flotation plant is in operation. Of a total of 4,114,856 oz. shipped, 20,221 oz. are credited to silver recovered from gold ores.

Refineries.—There were treated at southern Ontario refineries 1242 tons of ore and concentrates and 1483 tons of residue from Cobalt and outlying silver centres. Silver bullion recovered was 1,610,989 oz., worth \$1,394,599. In addition, arsenic, cobalt and nickel oxides and sulphates, nickel carbonate, metallic nickel and cobalt were produced. Of the latter, 22,752 lb. was used in the manufacture of stellite, a cobalt alloy used as a high-speed cutting tool. One feature of note is the great increase, 100%, in value of

cobalt metal and oxide due to the increasing uses and demand for these products.

Nickel-Copper.—Production from Copper Cliff and Coniston smelters for the quarter shows a small decrease. Ore was raised from the Creighton and Crean Hill mines of the Canadian Copper Co., the Alexo, and the following mines

MAP SHOWING MINING DISTRICTS OF NORTHERN ONTARIO

of the Mond Nickel Co.—Garson, Victoria No. 1, Worthington, Levack, and Bruce. Of a total of 354,689 tons extracted, about 70% came from the large and rich Creighton orebody. There was 325,386 tons of ore smelted in the period with a resulting product of 17,992 tons of nickel-copper matte.

The British America Nickel Corporation has acquired a site to erect its \$1,000,000 refinery on the Quebec side of the

Ottawa river between Alymer and Hull. The new refinery of the International Nickel Co. of Canada at Port Colborne is nearing completion.

Iron Ore and Pig-Iron.—Shipments of iron ore were made from the Helen and Maggie mines of the Algoma Steel Corporation. Hematite ore from the Helen is shipped to the Maggie, where it is mixed with siderite ore and roasted. The entire shipments from the Maggie went to the Sault blast-furnaces. From Moose Mountain Limited, Sellwood, shipments were made of magnetic concentrates, briquetted and converted to hematite in a kiln. Only 447 long tons was exported to the United States during the quarter.

At Sault Ste. Marie, Port Colborne, Hamilton, and Deseronto, eight blast-furnaces were in operation. The quantity smelted was 34,552 tons of Ontario ore and 260,476 tons from the United States. As shown by the table, the output of pig-iron was considerably less than for the corresponding period last year.

Molybdenite.—Molybdenum ore, to the extent of 1295 tons, was treated by the Mines Branch, Ottawa, and by the Renfrew Molybdenum Mines, Ltd., at Mount St. Patrick. The output of the latter is shipped direct to France. There are works at both Orillia and Belleville for the production of ferro-molybdenum.

Lead.—The entire output of pig lead resulted from the operations of the Galetta lead mine and smelter owned by the James Robertson Estate, Montreal. During the quarter 3347 tons of ore was mined. The smelter operated during the last few days of March only. Operations by the Kingston Smelting Co. ceased in December of last year.

GILBERT, MINNESOTA

Operations in the Iron-Ore Districts.

Stripping at the Mace mine is being done by Butler Bros. and will soon be completed. The work consisted of moving the overburden from over some pillars of ore left during underground operations. A small Marion revolving shovel was used and one locomotive for the dump-cars.

The Republic Iron & Steel Co. started work on the large pile of ore accumulated during the winter from underground workings of the Bray mine. A steam-shovel was received some days ago from the Kinney mine, and was put to work. A large body of ore has been developed in the Gordon, and this as well as new ground will be thoroughly drilled. There are now seven drills on the Gordon and Bray properties.

Work has been started on the Sargent property (160 acres) of the Wisconsin Steel Co. west of Keewatin. This new mine is west of the Bray. A great deal of exploration has been done during the past three years and a large tonnage of ore has been exposed by diamond-drills. This mine will be worked by both open-pit and underground systems. The former will not be a large one. Underground work will be of the usual standard in this district. There will be the regular four-compartment shaft sunk to about 180 ft. There is little prospect of the Sargent mine shipping any ore this year, but it will be on the list next season. B. W. Batchelder is superintendent.

The war gardens at the Bray, Gordon, Sargent, Mace, and Bennett mines have been ploughed and harrowed, and are all ready for seeding as soon as the ground is warm enough. The soil is in much better shape than last year, and chances are much better for a large crop of vegetables. There is enough land at the different mines so that every family will have an opportunity to raise all of its winter supply.

Drilling for iron ore will be soon started in the northern part of Itasca county, northern Minnesota. Indications are good. Samples so far are of the Vermillion type, and assays have been unusually high in iron. It is expected that drilling will start early in June. Many prominent mine operators have already visited this new field.

PLATEVILLE, WISCONSIN

Zinc-Ore Prices, Labor, Concentrate Reserves, Lead, Pyrite, and Production Conditions in May.

Operating conditions in the Wisconsin field at the beginning of May were unsatisfactory and unprofitable. The price offered for 60% zinc concentrate was under \$50 per ton, with premium grades of refinery ore as high as \$52 per ton. Low-grade producers were offered less than \$20 per ton for 30% separator product, claimed to be under production cost. Second-grade ores were in better demand, with the range down to \$45. This situation was as distressing in the Joplin district of Missouri, but operators there were more alert to their interests, and meetings held at Washington resulted in the appointment of an allocating committee, with privileges that enabled adjustment of prices (\$75) on zinc concentrate entering into the manufacture of rolled or sheet-zinc. About mid-month the price on a certain quantity of high-grade refinery material was advanced to \$65 per ton; the remainder of the month brought the top price paid to \$70.25 for Wisconsin ore. Standard 60% product not entering into the manufacture of rolled zinc received a boost, the base going to \$60, with the range on second grades down to \$45. This range was in effect at the close of the month.

Labor conditions, acute early in the month, were further aggravated by the draft. The immediate result of this additional exodus of able-bodied men was reduced operations at nearly all of the large properties and the shutting-down of mines at nearly all points in the field until capacity was reduced to about 60% of normal.

Restricted deliveries of concentrate augmented a fair reserve in bin at the beginning of May, until near the close of the month there had accumulated the largest reserve ever known in the field, conservatively estimated at 7500 tons. Individual instances were acknowledged by officials showing over 3000 tons held by the Block-House Mining Co. of Platteville, 2000 tons by the Frontier Mining Co. of Benton, and 1500 tons in the Shullsburg district. This stock served to slow-up buyers, it being patent to smelter representatives that there was sufficient blende available for their demands for some time to come, and that the surplus would rather be increased than lessened.

Mine development was brought to a halt at all points in the field, and except where mills were well along toward completion, building and mine equipment was suspended. Drilling continued at a fair rate in the Mifflin, Benton, New Diggings, and Galena districts, and satisfactory discoveries of new orebodies were reported. Refineries were active most of the month.

Offerings for lead ore were well maintained through the month. The price opened at \$80 for 80% metal content, advancing gradually under good demand to \$85 per ton base, at which figure the month closed. Some ore was sold, but not much, producers being content to hold for better prices. With a lower output of zinc there came a reduced recovery of lead. Careful tabulation showed that there must have been in reserve at the end of the month 2000 tons of lead ore.

Shipments of pyrite showed a decided increase over previous months, following large demand for sulphuric-acid manufacture. The reserve was entirely eliminated. No crude ore was offered for sale, but the advance in price of pyrite to 27c. or better per unit of sulphur, and the prospect of a steady demand at fair prices, stimulated the work of exploration at several points. In the Montfort field, where large deposits of iron pyrite (marcasite) are known to exist, seven drill-squads were at work all the month in a small area, and extensive discoveries were announced. Local capital is behind the new undertaking, but it will require several months before deposits can be reached and mined successfully, so that the refineries will be depended

upon to supply such ore as will be made available from electro-static zinc-ore separation.

Shipments totaled 18,587 tons of zinc-blende, 472 tons of lead, and 483 tons of pyrite from mines to separating plants in the field, and from mines to smelters direct during May.

The gross recovery of raw concentrates from mines totaled 20,049 tons, and net deliveries out of the field 13,806 tons. The Mineral Point Zinc Co. received 7595; Grasselli Chemical Co., 4893; Wisconsin Zinc Co., 4414; National Separators, 2730; American Metal Co., 1304; Linden Zinc Co., 1190; Illinois Zinc Co., 632; M. & H. Zinc Co., 572; American Steel & Wire Co., 532; Lanyon Zinc Co., 188; and Benton Roasters, 118 tons.

NEW YORK

Transactions in Liberty Bonds.—Financial Situation.

The continued drop in value of the last two issues of Liberty Bonds in the open market is a matter for further discussion. Conjectures for the reason of the downward tendency are numerous. The recent low prices of 93.52 and 96.36 for the 4s and 4½s, respectively, indicate abnormal selling. The reason should be sought to prevent lack of confidence in future issues, if for no other cause. It has been suggested that liquidation has been due, in large measure, to the transfer of money from Liberty Bonds to farm-loan issues, which carry a higher rate of interest; but it is unlikely that there is any extensive movement in this direction. Another phase of the matter seems to have escaped attention. The efforts made by the Committee to reach and influence the greatest number of wage and salary earners were unparalleled, and resulted in complete success. The immense increase in the number of subscribers, particularly in the matter of the smaller bond denominations, indicate this success on a per capita basis. The educational campaign to teach the duty to purchase, to inculcate the idea of privilege in assisting the Government, and to emphasize the soundness of the securities behind the bonds, was carried out with a vigor that reached all quarters and resulted in a response from all sections of the community. As a sales effort the campaign exceeded all expectations; but with the last sale all interest in the subscribers, as subscribers, seemed to cease. Information as to the current market-value of the bonds is disseminated in all newspapers, and millions of uneducated people are wondering why the bond they bought only a few weeks ago for \$100 is now selling for only about \$96. The necessity of allowing Liberty Bonds to mature, and the lack of patriotism shown by those who part with them, except under necessity, are matters yet to be emphasized to the people. The result is that an indeterminable number of bond holders are the victims of crooks and sharpers who prey on those whose education, in what was to them a new world of finance, ceased as soon as they had paid the money. The modus operandi of these gentry is as follows: No difficulty is experienced in finding out who holds bonds, as subscribers were asked by the Committee to advertise the fact by wearing a button. The next step is to get into touch with the victim and, in glowing terms, indicate the advantages of coming in 'on the ground floor' and purchasing a block of stock in a new company with amazing undeveloped resources (now paying a paltry 12 or 15% interest) at \$1 or so a share. The interest rate is, figuratively speaking, a fleabite; but invites mental comparison with the 4½% paid to Liberty Bond holders. The next step is to promise the victim that the shares can be sold in about three months time, when the stock will be placed on the market, at double the price now offered, thus insuring a 200% return of the money, plus the dividends received in the meantime. Then follows a specious and carefully-prepared argument in which the victim is eulogized for his patriotism in buying Liberty

Bonds, and told that, now that the Government has the money required, it is immaterial what he does with the bonds. He is reminded that the interest received on his money is only 4½% and that the market-value of the bonds is decreasing daily. As a further incentive to get him to part with his bonds in exchange for a block of worthless shares he is told that full par value will be allowed in any such transfer. How many holders can be hoodwinked by such a yarn is a matter for speculation, but the fact remains that the scheme is in full operation. By what devious routes such bonds travel before they reach the open market, and in what quantities they are disposed of, would prove interesting reading. For the benefit of those who realize, without being told, that both duty and patriotism involves the holding as well as the buying of war bonds it is hoped that steps will be taken to prevent liquidation from such a cause as the one mentioned. The protection of the uneducated or gullible holders of Liberty Bonds against the machinations of bogus oil-well or other sharks should be a post-campaign feature of the next issue.

Price movements during the past week afford further proof that depressing news has little or no effect, whereas good news results in an all-round appreciation. The total volume of sales still shows a considerable decline from previous years, and this is largely due to national-bond holding. Saturday's (June 8) sales in stocks were less than half the number disposed of on the same date last year; whereas bond sales amounted to over 3½ times the number. The increased activity in bonds is directly traceable to Liberty Loan movements. Buyers are now to the fore, and the 4s of the second Loan moved recently from a low of 93 to a closing quotation on Saturday of 95. The 4½s of the third Loan also advanced.

OTTAWA, CANADA

Iron, Steel, and Coke Situation.

The problem of securing sufficient steel for munitions and for much-needed construction is engaging the close attention of the Canadian government. Last week a number of representatives of the principal steel manufacturers conferred at Ottawa with the Government and the Imperial Munitions Board. The commandeering of the entire steel output for war purposes was considered, but the objection was put forward that it would dislocate many departments of the plants and severely injure export trade, and, in the meantime at any rate, less drastic measures have been adopted. In order to encourage the establishment of new iron and steel industries, the Government has decided to purchase all pig-iron produced in Canada by any new blast-furnaces erected during the next two years. It will agree to take all of the output for three years at a price to be governed by market-conditions at the time. Some of the manufacturers urged the granting of a subsidy, but after full consideration it was decided that this would be unwise at present. The Dominion Steel Corporation has done much preparatory work in connection with the construction at Sydney, Nova Scotia, of a ship-plate rolling mill in accordance with its agreement with the Government. It will have a capacity of 100,000 tons per annum, of which the Government will take from 50,000 to 75,000 tons yearly for a 5-year period. The corporation is also erecting a new coke-oven plant, comprising 120 by-product ovens of the Koppers type, 11.3 tons each, with a total guaranteed output of 1320 tons daily on 16-hour coking time. The first battery of 60 ovens will be in operation this month, May, and the second unit a month later. The present plant, consisting of 620 Otto Hoffman by-product 4 and 6½-ton ovens, is badly out of repair, giving an output of only 1600 tons per day. As soon as the new ovens are in operation the others will be repaired. The present coal-washer will be replaced by a new Simon-Carves plant, which will give better results.

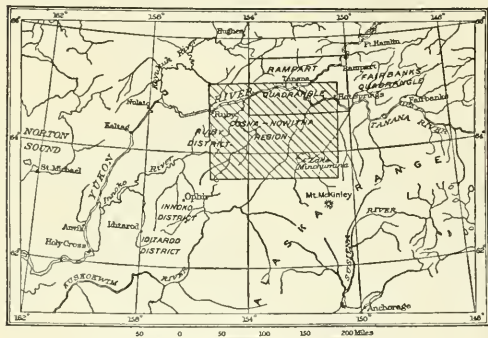

ALASKA

Juneau.—Alaska Gold in May treated 101,200 tons of \$1.11 ore. Extraction was 81.24%. Tonnages since January are, 179,300, 140,305, 150,093, 125,435, and 101,200, respectively.

The Alaska Juneau company's 8000-ton mill is shut-down. As it is not economical to operate it on a 1000-ton basis the old 40-stamp pilot-mill is handling all the ore available at present. There are 175 men employed, but P. R. Bradley states that 350 are needed.

Ruby.—In Bulletin 667 (54 pages) of the U. S. Geological Survey, the Cosna-Nowitna region is described by Henry M. Eakin. This area has produced no mineral wealth. Auriferous gravels have been found at a few places, but no placers justifying exploitation have been discovered. The placers are most likely to be found on streams where the overburden is probably very deep, therefore the field is not attractive to

MAP SHOWING SITUATION OF COSNA-NOWITNA REGION

prospectors. Some of the geologic formations are similar to those that are gold-bearing in districts on the north-east and north-west. Search for gold in streams that cross the granite contacts is most likely to be successful. The region as a whole is fairly accessible, many of the streams being navigable for small boats. It is well timbered, and includes much fertile land similar to that near Fairbanks.

ARIZONA

Ajo.—Considerable water is being encountered at a depth of 140 ft. in churn-drilling at the Little Ajo property.

Bisbee.—The Copper Queen Branch of Phelps-Dodge Corporation announces that commencing July 1 all employees will be given a yearly bonus of \$100 at the end of one year's continuous service, to be increased for each succeeding year. The Calumet & Arizona and the Shattuck Copper companies announce a similar plan. Phelps-Dodge paid \$6 per share on June 20.

Globe.—Old Dominion produced 3,239,000 lb. of copper in May, against 2,814,000 lb. in April. On June 28 the company pays \$1 per share, making \$2 for the current year.

Jerome.—On May 21, Judge Lyman of Maricopa county, in

the Superior Court of Yavapai county at Prescott in special session, granted the petition of the minority stockholders of the Hull Copper Co. and appointed R. H. Hetherington receiver of the company and of the block of shares held by Charles W. Clark, trustee. The appointment was made over the objections of the attorneys for the Hull Estate and Clark, who gave notice that the matter would be appealed to the Supreme Court and signified their intention of furnishing the supercedas bond in the sum of \$1,000,000 in order to stay the process of transferring the Clark and company's holdings to the receiver. On May 31 attorneys representing the Clark interests filed the supercedas bond of \$1,000,000 required by the Court, thus having the effect of staying the proceedings of turning over the property of the company to the receiver. The bond was signed by W. A. and Charles W. Clark as principals with the following sureties: E. W. Wells, M. B. Hazeltine, Mrs. Hugo Richards, J. I. Gardner, Jerry W. Sullivan, Henry Brinkenmeyer, C. A. Peter, and O. A. Hesla, all of Prescott, and Walter C. Miller of Jerome.

Superior.—Magma Copper pays a dividend of 50c. per share on June 29.

COLORADO

Breckenridge.—All the dredges in this district are working full time. Tonopah Placers has three, the French Gulch one, and the Powder River company of Oregon one boat.

Crisman.—At the Yellow Pine claims 18 sets of lessees are extracting a large tonnage of silver ore. Numbers of old silver mines in this district are being re-opened.

Denver.—Mine operators of this State will protest against the increase in freight-rates. They consider that production of gold, silver, lead, zinc, and copper will drop at least 50%. The smelters have already increased their charges on bullion shipped from them. Cripple Creek will be considerably affected. According to the State Commissioner of Mines, Fred Carroll, there is 10,000 tons of bullion shipped out of Colorado every month. The freight increase is about \$6.50 per ton, or a total for the month's business of \$65,000. Adding to that amount the accumulation of increased costs due to the general order, the increase for an entire year will be well in excess of \$2,000,000. Comparing these figures with the aggregate net earnings of \$3,200,000 for 1917, or rather deducting that amount, will readily show that the producers find it almost an impossibility to continue operations, even for needed war minerals and metals. Dividends paid in Colorado during 1917 were the leanest for 10 years. A few bonanza properties like the Cresson at Cripple Creek, the Wellington at Breckenridge, and the Tomboy at Telluride were exceptions to the rule.

IDAHO

Kellogg.—The Coeur d'Alene Antimony company is re-modelling its mill, putting in a flotation plant, using the K. & K. apparatus. In bins is 2000 tons of ore. A good deal of ore is said to be blocked out in the mine, which is on Pine creek.

Moscow.—An extensive geological survey, requiring the entire summer, is under way by the Idaho School of Mines, with L. C. Livingston in charge. Search is being made for

tungsten, molybdenum, mercury, tin, platinum, and mica. All promising prospects are being examined and samples of ore thought to contain any of these minerals will be analyzed.

Mullan.—The National copper mine has been closed indefinitely, with no plans for the future. During May the 500-ton mill dressed ore averaging 1½% copper and 4 oz. silver per ton. According to the manager, Charles McKinnis, ore on the 1500-ft. level is more oxidized and leached than in the upper levels. The Snowstorm fault, which cuts the National vein, is considered responsible for this condition.

Wallace.—Statements filed with the County (Shoshone) Assessor show the following results for 1917 from Coeur d'Alene mines, compared with 1916 and 1915:

Company	—Ore mined or shipped, tons—			Gross Value			Profit		
	1917	1916	1915	1917	1916	1915	1917	1916	1915
Anaconda (Douglas)	7,799	\$ 346,718	\$ 23,477

*Loss.

MISSOURI

Joplin.—Concentrate production of the region last week was 6440 tons of blende, 107 tons of calamine, and 1168 tons of lead. These averaged \$47, \$33, and \$87 per ton, respectively. The total value was \$432,152, of which Missouri contributed \$214,477. Total for 23 weeks is \$10,741,558.

The Essential Producing Co. of Miami and Kansas City is the name of a new company which proposes to drill leases, operate mills, and a smelter, etc. A 150-ton mill has been secured in the Lawton-Vaco district, and is recovering 6% blende and lead. Between Hockerville and St. Louis the company has cut rich ore by drilling, and is to sink a shaft. Also, the company has 600 acres of oil leases in the Chelsea-Nowata field. Well-known Missourians and Oklahomans are interested, with C. R. Hemmenway as general manager.

NEVADA

Carson.—The Industrial Insurance Commission has announced changes in compensation and accident benefit rates for the State, effective July 1. During 1917 the mining companies contributing to the fund paid a compensation rate of \$3.50. During January, February, and March of the current year this rate was reduced to \$3.25. The rate in April, May, and June was fixed at \$3, and during July it will be \$2.75, the rate being based on each \$100 of payroll. The milling rate up to June 20, 1918, will be \$2, and beginning July 1 it will be \$2.25. During April there were no fatalities, while in previous months the average was six.

Graphite is reported as having been found just beyond the hot springs north of the city by C. R. Dake. The Black Hope and O. K. graphite mining companies have been organized.

Goldfield.—The Goldfield Great Bend Mining Co. has issued a report covering the period of February 1, 1916, to April 1, 1918. During this time 2388 tons of ore was sold averaging \$38.62 per ton. Mining, freight, smelting, etc., total \$61,215. This deducted from the gross value, \$92,203, left a profit of \$30,988. Development—4633 ft.—cost

\$54,578. In May 1916, pumping was started, and the shaft was unwatered to 420 ft. From the 250-ft. point the shaft was full of debris, and had to be re-timbered to the 500-ft. levels. Difficulties at 400 ft. made necessary a change to the 236-ft. level, where a good deal of work was done. In January 1918 this level reached the 418-ft. Lockhart shaft, and it is intended to thoroughly prospect the ground adjacent. On the 160 and 236-ft. levels there is enough ore showing to keep a 25-ton mill at work, so tests are to be made as to the best method of treatment. Although the period resulted in a loss of \$25,529, the company's assets total \$23,248, of which \$1585 is cash.

Goodsprings.—The Yellow Pine company has arranged a contract with the Empire Zinc Co. for 1200 tons of mixed

ore per month.

Mill City.—There are 150 men employed in this new tungsten district. The Pacific Tungsten Co. is sinking four shafts. Regular shipments are sent to the mill at Toulon.

Tonopah.—The present situation at Gold Mountain is said to be very promising. The Tonopah Divide is sinking to No. 3 level. The Brounger Divide is cross-cutting from the 170-ft. level. Divide Extension is making good progress at 150 ft. The Dividend will sink to 250 ft. before opening out. The Hasbrouck has driven its tunnel over 40 ft. In foot-wall formation, assaying from \$2 to \$4 per ton.

OKLAHOMA

Picher.—Oklahoma districts last week produced 4742 tons of blende and 935 tons of lead, valued at \$217,675.

The Eagle-Picher company is trying mules in its mines.

OREGON

Gold Hill.—The Rainier Mercury Co. has found a large vein of good cinnabar in the Meadows district, 12 miles north of Gold Hill. They have a 12-pipe furnace at work, and shipped 40 flasks last week.

Jacksonville.—The Blue Ledge copper mine is employing 65 men, shipping 150 tons of ore per week. This assays 12%. The haulage-charge is \$10 per ton.

Waldo.—The California Chrome Co. has purchased from George S. Barton and associates of Grants Pass 24 chrome claims on Smith river near the Josephine County-California State line. Much development has been done, and a large tonnage is available for shipment by way of Crescent City, California.

UTAH

Bingham.—On July 1 Bingham Mines pays 50c. per share. This amounts to \$71,500, making \$393,250 to date.

Shareholders in Montana-Bingham are said to be dissatisfied with the present state of affairs and are to demand a change.

Parke City.—Production of this district in May was 10,165 tons of ore worth \$500,000. The Ontario headed

the list with 3440 tons. This company pays 50c. per share on July 5. This is equal to \$75,000, and makes \$15,037,000 to date.

On June 22 Tintic Standard company paid 6c. per share. This equals \$70,480, and makes \$188,980 to date.

Tintic.—More manganese is to be extracted by lessees in the Chief Consolidated mine at Homansville. The present daily output is 10 to 15 tons of 45% ore.

The Utah Zinc Co. at West Tintic is producing rich lead-zinc ore, also some manganese.

The Iron King shaft in Eureka district is down 450 ft. below the tunnel-level, equal to 800 ft. from surface, in promising formation.

The Tintic Milling Co. is treating 200 tons of ore daily, somewhat below capacity. A recent bullion shipment amounted to 66,000 lb., valued at \$50,000.

WASHINGTON

Chewelah.—United Copper recently shipped 42 tons of ore which assayed 16% copper and 102 oz. silver per ton. This was obtained by sorting on the 1250-ft. level. May shipments were 2 cars of crude ore and 14 of concentrate.

Olympia.—"Manufacturing Opportunities in the State of Washington" is the title of a 240-page bulletin issued by the Bureau of Statistics and Immigration. The mineral resources—non-metals—are covered by Henry Landes, State Geologist, and metals by Milnor Roberts, dean of the College of Mines at Olympia. Coal is the most important non-metal produced. The industry employs 5000 men, and accounts for half of the State's mineral output. Clay and cement are also important. The precious-metal yield is not large, but capable of expansion. Copper is widely distributed, largely in regions difficult of access. Lead and zinc show good increases of late. The U. S. Bureau of Mines has an experiment station at Seattle, where much investigation is under way.

Valley.—The International Portland Cement Co., operating at Irvin, east of Spokane, is calcining magnesite from mines near Valley. The kilns are dealing with 1000 to 1500 tons per week, producing half of this quantity of calcined material, the rate of reduction being about two into one. C. A. Irvin is manager.

CANADA

British Columbia

Ainsworth.—The Florence Silver M. Co. is now working profitably. Net earnings in April were \$17,960. Concentrate assays 20 to 26 oz. of silver and 70 to 80% lead. On July 1 an electric locomotive will start hauling 12 ore-cars on No. 3 tunnel-level.

Ladysmith.—The custom smelter here is to be blown-in about June 20, according to W. J. Rattle, general manager for the Ladysmith Smelter Co., who returned to Seattle recently from New York, where satisfactory financial arrangements were made for the resumption of operations. This plant was active for a while last year, but was closed to permit of re-organization and to provide for a continuous supply of ore. Both of these objects have been accomplished. The company will operate under lease and bond what is known as the Willow Grouse claims in the East Sooke district, Vancouver Island, from which several satisfactory shipments have been made. There are 2000 tons of coke on hand at the smelter as well as 2000 tons of basic copper ore, which has been held over pending the securing of silicious ore for fluxing. The Hon. William Sloan, Minister of Mines, has taken a keen interest in the effort to develop conditions that would warrant the smelter's re-opening, not temporarily but with reasonable assurance of being able to continue, and he is satisfied that the small mine operators of the Island and of the Coast sections of the mainland of the Province will find the smelting facilities

thus provided a real boon. The resident engineers for the Coast mineral survey districts—George Clothier and W. M. Brewer—report that there should be several mines developed during the coming season to a sufficient extent to

assure regular shipments of such size as to keep the plant working to capacity.

Trail.—From January 1 to May 21 the Consolidated M. & S. smelter here reduced 165,832 tons of ore. Le Roi of Rossland contributed 41,101 tons. Sullivan, 36,575; Center Star, 34,164; Emma, 15,062; and mines in Washington, 3228 tons.

The Consolidated M. & S. Co. pays 2½%, equal to \$261,936, on July 2. This makes \$4,501,723 to date.

Victoria.—There is an area on Vancouver Island, approximately 3296 square miles (the whole of the island comprising only 17,000 square miles), which is termed the Esquimalt & Nanaimo Railway Belt, there are applied both company and Provincial regulations for mining operations. This dual control has so complicated titles to claims within the section that development within its limits has been seriously hampered. With a view to curing this undesirable position the Minister of Mines at the last session of the British Columbia Legislature asked for and obtained authority to enter into negotiations with the company looking to the establishment of a single authority in regard to the minerals of the E. & N. Belt, that authority to lie in the hands of the Province. It may be said, by way of explanation, that these lands were given the original builders of the railroad as a bonus for their enterprise.

The Strathcona Park Amendment Act is a measure passed by the 1918 Legislature of British Columbia which is of special interest to prospectors of the North-West. This opens to exploration a highly-mineralized area of Vancouver Island comprising 530,066 acres. It was closed some years ago in order that it might be preserved in its natural state as a National park. It is claimed by the present Government that development of its mineral cannot interfere, at any rate to any material extent, with its value as a park, consequently permission is now given to miners to record claims within its limits, and to proceed with mining in the usual way.

Ontario

Cobalt.—The Ophir Cobalt Mines Co. is doing interesting work and a recent circular is optimistic as to the future. A winze is being sunk below the 440-ft. level, near where a shoot of 1600-oz. silver ore was opened.

MEXICO

Durango

Batopilas.—Another rich silver shoot is reported as having been opened in the Batopilas mine.

Sonora

Cananea.—Greene Cananea Copper Co. has issued its report for 1917, including its subsidiaries, the Cananea Consolidated Copper Co. and the San Pedro Copper Company.

The properties were operated from January 1 to June 22, after which they were closed on account of Federal and State government action. A better understanding was reached with the authorities, and work was resumed on December 10. At present all plants are in operation. Sales of metals, etc., realized \$9,392,639. Expenses, including \$643,751 for administration and American taxes, and \$842,766 for Mexican bullion taxes, amounted to \$6,623,137. After charging depreciation with \$350,455, and adding \$78,842 for interest, the net income was \$2,497,888. The surplus at end of 1916 was \$9,504,979, and at end of 1917, \$8,048,652. Four dividends absorbed \$3,954,215. Current assets total \$8,405,579, and liabilities \$892,384.

Development at the mines of Cananea Consolidated amounted to 26,027 ft., and at the San Pedro 4824 ft. More ore was exposed than extracted. The most important development, though not the largest, was near the Campana shaft of the Sierra de Cobre mine, in a hitherto unproductive zone of large extent.

The concentrator dressed 171,202 tons of ore, 70% by flotation. The smelter reduced 481,632 tons of copper-bearing material. Results may be tabulated as under:

	Cananea Consolidated	San Pedro
Ore mined, tons.....	574,582	56,924
Copper output, pounds.....	24,711,204	2,658,014
Silver, ounces	655,656	122,137
Gold, ounces	3,804	723
Recovery per ton:		
Copper, per cent.....	2.273	2.526
Silver, ounces	1.153	2.486
Gold, ounces	0.006	0.013
Cost of copper, cents per pound	17.951	12.692

The last item includes the shut-down expenses and taxes on production. There were 185 Americans and 3794 Mexicans employed.

All the properties and works are now owned by the Cananea Consolidated Copper Co. as of January and July 1917.

The Committee on Mineral Imports and Exports in Washington has finished the work for which it was formed, namely, that of formulating programs for the minimum importation of ores and minerals, in order to save shipping for war purposes, without crippling any essential industry. These programs have now all been formulated and approved of by the various Government departments interested and are practically all in effect. Therefore the Committee has thought best to terminate its existence as such. Routine work connected with questions arising from the enforcing of the programs will be handled by the former staff of the Committee under the direction of Dr. E. F. Gay of the United States Shipping Board, under whose authority the Committee was organized for the purpose above mentioned. The Committee consisted of Messrs. C. K. Leith, J. E. Spurr, and Pope Yeatman, representing the Shipping, War Trade, and War Industries boards. Messrs. Leith and Spurr remain in a consulting capacity to the Shipping Board as Mineral Advisors. In addition to this, Mr. Leith has been appointed Mineral Advisor to the War Industries Board from the standpoint of the conservation of shipping; and Mr. Spurr has accepted an invitation to take charge of the War Minerals Investigation Campaign for the Bureau of Mines. Mr. Yeatman continues in charge of the Non-ferrous Metals Division of the War Industries Board.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

Charles M. Becker is at Santa Fe, New Mexico.

F. L. S. Holland passed through San Francisco on his way from Arizona to Denver.

Albert Roberts, of the Minerals Separation company, returned here from Joplin and has gone to Seattle.

C. O. Lindberg of Los Angeles is at Washington on business in connection with the U. S. Bureau of Mines.

H. C. Buckminster, general manager for the New Idria Quicksilver Mining Co., California, is here from Boston.

Frank Daniels passed through San Francisco on his way to Pasadena, after investigating nitrate deposits in Mineral county, Nevada.

E. W. Bradley, Jules Labarthe, and Roy Bishop visited the Northwest Magnesite Co.'s mine near Chewelah, north of Spokane on June 11.

A. P. Bradley, metallurgist at the Murray plant of the A. S. & R. Co., near Salt Lake City, was married in San Francisco on June 6.

Fred. Searls Jr. has been promoted from the ranks to First Lieutenant, and is now instructor in a school of military engineering in France.

J. O. Elton succeeds Milo W. Krejci as assistant superintendent of the Boston & Montana plant of the Anaconda Copper Mining Co., at Butte.

B. S. Morrow has been appointed superintendent of concentration at the Washoe reduction works, at Anaconda, his place being taken by S. S. Rodgers.

Hallet R. Robbins has resigned his position as consulting metallurgist with the Granby Consolidated company to accept a commission in the Army. He is now at Washington.

G. Montague Butler has just been appointed Director of the Arizona State Bureau of Mines to fill the vacancy created by the resignation of C. F. Willis. He will continue to serve as dean of the College of Mines and Engineering, the position he has held for three years.

John W. Cotton has been wounded—only slightly, fortunately—in France, according to the casualty list of May 12. He is the son of John W. Cotton, of Railroad Flat, California, and enlisted in 1914 when only 19 years of age, serving in the Mexican campaign before going across with General Pershing's troops to Europe. He obtained his commission in December 1917, was promoted to First Lieutenant soon after arrival in France, and became Captain of a machine-gun battalion at the age of 23—a fine record, now sealed by actual fighting at the front.

C. B. Sprague died at Salt Lake City on June 7 in consequence of injuries received in an automobile accident. He devised the application of the bag-house for condensing fume from the copper-smelting furnaces at Murray and Midvale, in Utah, by suggesting the use of zinc oxide as a reagent to neutralize the corrosive substances that otherwise would destroy the bags.

Arthur R. Trench, business manager of the 'American Metal Market,' New York, for several years, and second son of C. S. Trench, of C. S. Trench & Co., metal-brokers, was accidentally drowned at Camp Petawawa, Canada, on June 1. Mr. Trench enlisted in the Canadian Field Artillery on May 1, 1917, and was promoted to sergeant in a few months. With many others of like rank, he was being retained in Canada for drilling recruits. He leaves a wife and three small children.

THE METAL MARKET

METAL PRICES

San Francisco, June 18

Aluminum-dust, large and small lots, cents per lb.	65-70
Antimony (wholesale), cents per pound	15
Copper, electrolytic, cents per pound, in carload lots	23 1/2
Copper, electrolytic, cents per pound, in small quantities	24
Lead, pig, cents per pound	8.07 1/2-9.07 1/2
Platinum, Government price, per ounce	\$105
Spelter, per flask of 75 lb.	\$110
Spelter, cents per pound	9 1/2
Zinc-dust, cents per pound	17 1/2

ORE PRICES

June 18

Antimony, 45% metal, f.o.b. California, per unit	\$1.10
Chromite, 35 to 48%, f.o.b. California, per unit	\$1.25-\$1.50
Magnetite, crude, California, per ton (nominal price)	\$7.00-\$8.00
Manganese, domestic, 35 to 54%, f.o.b. South Chicago, per unit (Government price, effective May 29)	\$0.86-\$1.30
Manganese, domestic, 35 to 54%, f.o.b. east of South Chicago, per unit (Government price, effective May 29)	\$1.01-\$1.45
(Manganese, domestic, penalty of 50c. to \$1 per ton for 8% and up to 25% silica, and bonus of 50c. to \$1 for less than 8 and 5%.)	
Molybdenite, per lb., 90% MoS ₂	\$1.25

According to Albert Burch, Crocker Bldg., San Francisco, representing the U. S. Bureau of Mines in investigating chrome, production of California this year shows a falling off. Miners are notified that the Government is not buying chrome nor financing development of chrome properties, as there is no appropriation for this, but the Government is aiding stimulation of output by the present investigations.

EASTERN METAL MARKET

(By wire from New York)

June 18—Copper is unchanged. Lead is inactive and nominal. Spelter is quiet though strong.

SILVER

Below are given official (not Government) quotations, in cents per ounce of silver 999 fine. In order to make prompt settlements with smelters and brokers, producers allow a discount from the Government price of \$1, hence the lower price. The Government has not fixed the general market price at \$1, but will pay this price (as from April 23, 1918) for all silver purchased by it. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the current rate of exchange.

COPPER

On September 21, 1917, the Government fixed copper prices at 23.50c. per lb. for large lots, and 24.67 1/2c. for small lots, effective until June 1, 1918. On this date the prices were re-fixed until August 15, 1918. Quotations in cents per pound are as under:

June	11.74	7.82	7.82	Dec.	7.53	6.49

Lead ore is stronger at Joplin, Missouri, the top price, basis of 80% metal, being up \$2.50 at \$87.50 per ton.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound. On May 23, 1918, the Government fixed prices until September for grade A spelter at 12c. per lb. for itself and the open market. Lower grades can make their own prices as usual. Sheet-zinc is fixed at 15c., and plate at 14c. per pound.

The zinc-ore market at Joplin, Missouri, has been slightly weaker, no sales of second-grade, basis of 60% metal, being over \$43 per ton.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. The Government is taking 40% of the United States quicksilver output, paying therefor \$105 per flask. Outside of this business the competitive market can make any price as usual. Prices, in dollars per flask of 75 pounds:

Date	1916	1917	1918	1916	1917	1918

Vulcan Detinning Co. reports for the first quarter of 1918 sales totaling \$335,472, against \$352,792 in this period of 1917. The net profit was \$14,988, compared with \$36,051.

ORES

Manganese: Indian ore has sold at a new high figure in the last week. One lot for forward delivery brought \$1.40 per unit. April imports of manganese ore were larger than had been expected. They amounted to 58,023 tons, or next to the largest of any month this year, and contrast with 19,300 tons in March. It has been arranged that sailing vessels will carry coal to the Central Railroad of Brazil and that 35,000 tons per month of ore will be allowed to be imported from there.

Eastern Metal Market

New York, June 12.

Some markets have advanced. The general tone in all but tin is strong, yet there has been no pronounced activity in any.

Copper conditions continue unaltered.

Tin continues to ease, but transactions have been very light.

Lead has been heavily bought by the Government and is higher.

Zinc is stronger and higher on light offerings and transactions.

Antimony has been more active and is higher.

The distribution of the entire iron and steel output of the country has been put into the hands of J. L. Replogle, Director of Steel Supply, by order of the War Industries Board dated June 6. No one in the trade fully understands the order, says 'The Iron Age'. Starting with the sweeping provision that no pig-iron or steel products shall be shipped except under priority certificates, the order provides that after all priority requisitions have been filled producers may supply their customers if the latter are on a preferred list which is to be sent out later as revised. Producers have thus far no direct or official notification of the new order. It is a fact that no accurate estimate exists or can be made of the Government's steel requirements. One official estimate is that the Government will take at least 85% of the output for strictly war purposes. Steel workers have been puzzled by the numerous reports in the past week, even though promptly denied, that the Government would take over the industry in an operative way; yet the resolutions of the War Industries Board expressly provide for the continued co-operation of the steel manufacturers' committee.

COPPER

General gossip is about the only material available for this paragraph in these days of a strictly controlled market. There is no concealing the fact that there is a good deal of dissatisfaction over the refusal of the price-fixing committee to advance the price of 23.50c. for copper as of June 1. Many believe it was urgent in view of all the facts and some expect a re-adjustment by August 15, or perhaps before. Your correspondent ran across an interesting rumor yesterday: It was to the effect that a proposition is being seriously considered at Washington, as the result of a suggestion of some producers, that 15% of the copper output be permitted to be sold at whatever price it will bring, the remainder to be distributed at the Government price of 23.50c. per lb. It is figured that the 15% would sell perhaps as high as 35c. per lb., thus raising indirectly the 23.50c. price of the rest about 1.75c. per lb. This would be an interesting experiment, but it is hardly thought likely to be carried out. Many think that some change in price-conditions is probable before August 15. The copper producers are to have another meeting on August 7. Copper demands are and have been large, and it is stated that producers are quite a little behind on deliveries due by June 1. Consumers are clamoring for copper, and some sellers have booked orders until August 15 at 23.50c., while others have done so subject only to a revision of price. As far as received May exports of copper produced by the smelters compare favorably with that of March and are higher than that for April.

TIN

The market continues to decline, and is considerably unsettled at the present writing, due largely to the fact that between Saturday of last week and Monday of this week the

Singapore price fell £23 per ton. As a result buyers are waiting. Late last week, or during the last three days, namely, Thursday, Friday, and Saturday, there was a little buying for future shipment from the Far East, which was sold at prices running down to 82c. per lb., which compares with transactions at 85c. a week ago. So far this week there has been practically no business reported. The spot market is nominal and unchanged at 90c., New York. The New York Metal Exchange reports tin arrivals from Pacific ports in May to have been 3210 tons, which, with the Atlantic port arrivals, makes the May deliveries total 4056 tons. The monthly average deliveries to June 1 this year have been 4459 tons, which compares with 3475 tons per month in the first seven months of 1914. Arrivals at Atlantic ports to June 11 inclusive, have been 275 tons, with 1300 tons reported as having come in at Pacific ports. Tin in London continues to decline. Yesterday spot Straits was quoted at £329 per ton, a decline of £17 per ton since last week.

LEAD

It has been expected for some time that the leading producers would advance its price. This took place the middle of last week when the American Smelting & Refining Co. advanced the price 3c. per lb., that is, to 7.25c., New York. It is reported that that interest did sell a little lead at the new level, but later withdrew from the market. An important feature of the past week has been the large buying by the Government, which is stated to have purchased large quantities and to have cleaned up most of the available supply except that of a few outside producers. As a result prompt lead is more difficult to get than for some time. The fact that Government needs come first has restrained the few that still have some lead from offering. It is stated that some lead was sold first prior to the purchase by the Government at a higher level than the A. S. & R. price. The market is strong and higher at about 7c., New York, for early delivery. A Lead Producers' Committee for war service has been organized at the request of Bernard M. Baruch with Clinton H. Crane as chairman, and Edward Brush, F. Y. Robertson, Harry L. Day, T. Wolfson, L. Vogelstein, Julius Loeb, and A. W. Dodd as other members.

ZINC

On light offerings the market has continued to advance and the tendency is still upward. Prime Western for early delivery is quoted at 7.37½ to 7.45c., St. Louis, or 7.62½ to 7.70c., New York, with light sales made at these levels. Demand is not strong, but there is a disinclination on the part of certain producers to quote, or else they have not the metal for early delivery. The Government is a heavy buyer of grade A zinc continually, and much lower grade metal has undoubtedly been re-distilled into grade A. For the third quarter 7.50c., St. Louis, or 7.75c., New York, is asked for prime Western. Dealers are reported as having done some buying of prime Western.

Sheet zinc is fixed at a 15c. per lb. basis, with plate zinc at 14c. per pound.

ANTIMONY

The market has again taken on life, with sales reported running up to 1000 tons and more. As a consequence quotations are higher at 12.75 to 13c., New York, duty paid, for Chinese and Japanese grades for spot and early delivery.

ALUMINUM

For No. 1 virgin metal, 98 to 99% pure, and for scrap metal, Government prices rule as follows: For 50-ton lots, 33c. per lb.; for 15 to 50 tons, 33.10c. per lb., and for 1 to 14 tons, 33.20c. per lb., effective until September 1.

Book Reviews

Mining Engineers' Handbook. Edited by Robert Peele. Pp. X-2375, ill, index. John Wiley & Sons, Inc., New York, 1918. For sale by the Mining and Scientific Press. Price, \$5.

This is the book that the mining engineers have been awaiting for many years. The civil engineers have had their Trautwine, the mechanical engineers their Kent, the electrical engineers their Pender, but the mining engineers have had nothing. The textbooks on mining were elementary compilations mostly of a general nature, and wholly unsuited to the purpose for which this new volume is designed. John Wiley & Sons have placed the mining world under obligations through their initiative in meeting so great a want, and they have been fortunate in securing the services of Mr. Peele as the guiding editorial spirit to translate the conception into achievement. His early experience in general practice in connection with important enterprises, and his long service as a professor of mining at Columbia University, have given him the right technical equipment and professional judgment for the task. The work is a compendium of many chapters contributed by a large number of the best known authorities. For example, the chapter on mineralogy is by Alfred J. Moses; that on geology and mineral deposits by J. F. Kemp; earth and rock excavation by Halbert P. Gillette; tunneling by D. W. Brunton and John A. Davis; prospecting, development, and exploitation by James F. McClelland; hoisting plant, shaft-pockets and ore-bins by William M. Weigel; drainage of mines by Robert Van Arsdale Norris; compressed-air plant by Richard T. Dana; electric power for mine service by George R. Wood; surveying by Charles B. Breed; underground surveying by Edward K. Judd; mine geologic maps and models by Reno H. Sales; mining laws by Horace V. Winchell; ore dressing by Robert H. Richards; ore sampling by T. R. Woodbridge; assaying by E. J. Hall; ore testing by J. E. Clennell and E. K. Judd; gold amalgamating and cyaniding by Edward L. Dufourey; mathematics and mechanics by C. H. Burnside; hydraulics by J. K. Finch; engineering thermo-dynamics by Edward D. Thurston Jr.; steam engines, pumps, turbines, and gas engines by H. L. Parr, E. D. Thurston Jr., and A. L. Herrick; electrical engineering by Walter J. Slichter; and elements of structural design by J. K. Finch. We have selected only a few by way of illustration. The volume, as will appear from this, is widely inclusive, corresponding to that extraordinary variety of engineering talent that is demanded in the mining engineer; in fact, he is often referred to as 'all sorts of an engineer.' The scope is so broad that only by a corps of specialists could it be covered adequately. Previous attempts to provide a handbook have been restricted to narrow fields. No single author could compass anything as big as this. The present volume gives the data required by the practitioner as completely as the essentials of mechanical engineering are provided in Kent's invaluable handbook, or as the fundamentals of electrical engineering are presented in Pender's *vade necum*. The art of mining engineering, and the chief contributory sciences, have been assembled for use in this valuable work. The ordinary questions arising in daily practice are answered with such fullness that only where problems of a special nature are involved will it be necessary to consult more extended treatises. It is in the best sense a ready assistant in the routine operations of the mine and the treatment-plant. The illustrations are particularly meritorious, being in most cases carefully executed working drawings, taken from the best practice. Formulas for the commonly recurring calculations in the various phases of engineering are given abundantly, together with the usual mathematical tables, logarithms, trigonometric functions, and other data of like nature. There is also a compendium of chemical

notes and tables, and other chapters are devoted to sanitary engineering, welfare equipment, and the application of modern requirements for safety. The appearance of this book is an event of real importance, and it will be heartily welcomed by the profession.

Sulphuric-Acid Handbook. By Thomas J. Sullivan. Pp. XIII, 239, index. McGraw-Hill Book Co., Inc., New York, 1918. For sale by the Mining and Scientific Press. Price \$2.50.

Never before has so great a popular interest been taken in sulphuric acid; this is because the demand has grown to such enormous proportions as a result of the War. Indeed it has grown far beyond the capacity of the equipment available. It is not long ago that firms in the East, including some of the greatest chemical manufacturers in the world, were forced to place orders in San Francisco for acid in car-load lots at a spot price of \$125 per ton. The fact that now, when the demand is even greater, the price of acid in the East is about \$25 per ton for the 60°B. grade, constitutes a measure of the response that has taken place in the building of new plants since 1916. No good modern textbook on the manufacture of acid has been available to meet the demand occasioned by the increasing interest in this branch of technology. Lunge's standard work is a monumental treatise, but it cannot be said to represent the details of the industry as practised at the leading plants today, where modern engineering has been applied. A book on the subject by Mr. Sullivan, who is an acid expert connected with a subsidiary of the New Jersey Zinc Co., will be widely welcomed. It is essentially a *vade necum* for the work's chemist; giving elaborate tables of specific gravities corresponding to readings by Baumé and Twaddle hydrometers; acid-tables for sulphuric, nitric, and hydrochloric acids; physical constants of sulphuric acid; specific gravity and per cent of free SO₃ as units in fuming sulphuric, and equivalents in H₂SO₄ as units; testing for specific gravity; acid calculations; definite acid mixtures, or so-called 'mixed acids'; melting and freezing points of sulphuric acid; tension of aqueous vapor; determination of SO₂ in burner gas; qualitative and quantitative analyses of sulphuric acid; calibration of storage tanks, and a large number of tables of areas, volumes, weights and measures, and the like, including tables of anti-freezing liquids. Some of the latter tables are so readily accessible in general engineering and chemical handbooks that their insertion here may seem superfluous, especially since space has not been given to some features that we think would have been appreciated, such as structural details of towers, chambers, coolers, and the multitude of special appliances found in an acid-plant. We think these would be useful, as well as data on pyrite and sulphur-burning; fan performance, flow of gases of varying composition through flues, cooling towers, and so on. Moreover, it would add to the completeness of the manual to have a brief outline of procedure in the manufacture of chamber and of contact acid, as well as the technique of acid-concentration. It is an admirable book, and meets a real want. That it might be added to advantage does not minimize the fact that it stands quite alone in its field, and that the student and practical acid-maker will here find assembled the information required to make easier the work in the plant and in the laboratory.

Tabular Classification of Igneous Rocks. By Victor Ziegeler. Department of Geology, Colorado School of Mines.

This is a small wall-sheet or diagram, showing 134 rock species. It is in the form of a key, based upon co-ordinates showing on the abscissas the facies and mode of occurrence, and on the ordinates the mineralogical composition, together with the accessory minerals and the average chemical analysis. It is exceedingly simple and useful.

Company Reports

ANACONDA COPPER MINING CO.

Property: copper and zinc mines at Butte, reduction works at Anaconda and Great Falls, refinery and rolling-mill at Great Falls, coal mines and lumber mills, etc., all in Montana. Also the company controls the International Smelting Co., International Lead Refining Co., and Raritan Copper Works, operating smelters and refineries. In South America two subsidiaries, the Andes Copper Mining Co., and Santiago Mining Co., are developing mines.

Operating Officials: the list is so long that space is not available in this review of operations during 1917.

Financial Statement:

	1917	1916	1915
Sales of metal.....	\$109,055,593	\$96,097,709	\$61,473,677
Gross receipts, inc. metal on hand.....	156,205,157	118,190,046	87,273,886
Disbursements.....	118,706,777	91,647,708	67,806,191
Balance.....	\$37,498,380	\$56,542,338	\$19,467,695
Income from investments.....	2,749,083	2,350,641	112,922
Interest paid.....	526,275	951,144	984,233
Depreciation.....	5,387,437	7,113,463	1,900,578
Profit.....	\$34,333,751	\$50,828,372	\$16,695,806
Dividends.....	19,815,625	17,484,375	9,325,000
Surplus.....	14,518,126	33,343,997	7,370,800
Profit and loss surplus.....	62,913,988	48,395,862	15,051,865

Current assets total \$71,328,647, including \$32,966,589 for metals in process and on hand. Current liabilities amount to \$36,065,119.

Dividends: No. 66 to 70 were paid during 1917, amounting to \$19,815,625. Including \$4,662,500 paid in April 1918, the total to date is \$142,370,000.

Development: labor disturbances starting in June lasted well on toward the end of the year, seriously curtailing all operations. New work covered 34.61 miles underground, a decrease of 7.35 miles. Shafts were sunk depths aggregating 2089 ft. Results generally were very satisfactory. New head-frames, hoists, compressors, and other machinery was erected. Ventilation of the entire property is under way, and electric fans were installed having a capacity of 696,100 cu. ft. of air per minute. Shafts were fireproofed with metal laths and cement. The mines produced 4,193,624 tons of ore and 10,012 tons of copper precipitate.

Reduction Works: the various plants concentrated and smelted on company account 3,906,901 tons of copper ore, 17,130 tons of precipitate, and 257,850 tons of zinc ore. These yielded the following metals: 239,014,880 lb. copper, 50,624,524 lb. zinc, 8,368,180 oz. silver, and 58,545 oz. gold. This is a decrease of 67,000,000 lb. copper, 2,400,000 oz. silver, and 33,000 oz. gold, but an increase of 30,000,000 lb. of zinc.

General: The copper-leaching plant treated 598,370 tons of tailing, yielding 5020 tons of cement copper. A satisfactory method has been evolved for treating the complex residue from the zinc-leaching plant. The acid plant was enlarged by 50 tons daily. A new 525-ft. stack is being built of brick made from flotation residue. The 100-ton copper rod and 80-ton copper wire mill is now in operation. Manganese ore is being mined and sold. The company's coal mines yielded 1,055,000 tons, and the saw-mills cut 87,330,000 ft. of lumber. The Butte, Anaconda & Pacific Railway carried 6,800,000 tons of freight and ore, and 355,224 passengers.

A brief review of the subsidiary corporations reveals the following:

International Smelting Co.

The smelter at Tooele, Utah, treated during 1917, 320,510 tons of copper ore and 334,274 tons of lead ore, from which there were produced 17,385,090 lb. of fine copper, \$4,726,315 lb. of fine lead, 4,439,290 oz. of silver, and 31,495 oz. of gold.

The smelter at Miami, Arizona, treated 242,936 tons of

concentrates and 26,839 tons of purchased ore, a total of 269,775 tons, from which there were produced 138,762,411 lb. of fine copper, 201,860 oz. of silver, and 2954 oz. of gold.

International Lead Refining Co.

The refinery at East Chicago, Indiana, treated 41,682 tons of lead bullion from the Tooele plant, and 23,558 tons of purchased ore and bullion, from which there were produced 117,922,724 lb. of common and corroding lead, 11,525,365 lb. of antimonial lead, 5,259,738 oz. of silver, and 24,673 oz. of gold.

Raritan Copper Works

The refinery at Perth Amboy, New Jersey, treated for all companies during the year 209,557 tons of copper bullion and 5,806,924 oz. of silver bullion, from which there were extracted 411,933,742 lb. of fine copper, 19,938,375 oz. of silver, and 137,465 oz. of gold.

Andes Copper Mining Co.

The property consists of 5301 acres in Chile.

Sixteen drill-holes were finished during 1917, aggregating a total depth of drilling of 12,000 ft. showing an addition to previously developed ore of 5,434,081 tons of an average grade of 1.5411% copper. A shaft 90 metres deep was sunk and 3750 ft. of tunnels were driven in the main orebody to check prior sampling.

It is estimated that there will be 1500 employees, and provision is being made to house them in a comfortable and sanitary manner, in addition to which churches, schools—both American and Chilean—office buildings, etc., are under construction.

The Quebrada pipe-line, consisting of a 3-in. steel line 17 miles long, with terminal reservoirs, was brought into Potrerillos for the purpose of supplying the camp. The Asientos pipe-line, of different pressures, aggregating a total of 96 miles, bringing in the water supply to Barquito for the purpose of supplying the railroad, was completed. Construction progressed on La Ola pipe-line, about 35 miles long, which is to bring water to the mill-site for the purpose of operating the concentrator when completed.

The Potrerillos railway transportation system has been divided into four sections, namely: (1) wharf at Barquito to intersection with State railway of Chile, 2.85 miles; (2) junction with State railway to Pueblo Huidido (this section is owned by the Chilean government), 38 miles; (3) Pueblo Huidido to mill-site, 56 miles; and (4) mill-site to mine, 5.5 miles.

The last section is to be an electric railway, of which 2 miles will be the main adit of the mine, and 1.2 miles branch tunnels. The grade of this system will be uniformly 0.3 of 1%, starting over the storage-bins of the mine at an elevation of 9700 ft., and the mine end will be 1000 ft. below the surface. All these roads will be one-metre gauge. Of this system, the Barquito wharf, port works, and first section of railway were completed last year. Of the section from Pueblo Huidido to mill, grading for 45 miles was completed and 8 miles of track laid. Of the last 11 miles, the estimated amount of material to be moved is 335,000 cubic metres, and 11 tunnels are to be driven, aggregating 5850 ft.; 164,351 cubic metres, or 49% of material, was moved, and 910 linear feet of tunnels, or 15.5%, completed during the year. Of the mine tunnels forming part of this system, the following percentages were completed during the year: No. 1, 17.5; No. 2, 56; No. 3, 72.4; and main adit, 7.4%.

Santiago Mining Co.

As part of the activity of the exploration organization operating in South America, options had been secured upon Lo Aguirre mines, situated 20 kilometres west of the City of Santiago, Chile. The mines consist of five groups, comprising 500 acres, part of which were acquired by purchase from former owners and part by denouncement. The ore

occurs as a disseminated deposit. Development was begun in March 1914, and by the summer of 1917 there had been developed more than 6,000,000 tons of ore carrying from 1.75 to 3.5% copper. The average of all tunnel samples was 2.44%. The ore is of mixed sulphide and oxide character. It is believed that the orebody contains a much greater tonnage, estimates having been made showing the probability of 16,000,000 tons, but a little over 6,000,000 is all that was, at the close of the year, definitely developed.

Options had also been secured upon practically the entire ownership of the Africana mines, 3 miles east of Lo Aguirre mines. Here the ore occurs in vein formation. The mine was developed by means of a shaft to a depth of 220 ft., and by underground workings having a lateral extent of 350 ft., also by 12 diamond-drill holes intersecting the vein at undeveloped points varying in depth from 50 to 388 ft. The ore is high grade, running from 4½ to 9%, and is particularly desirable on account of its excess sulphur content, which, manufactured into sulphuric acid, can be used for leaching the oxidized ores of Lo Aguirre mines.

Comprehensive tests were made on ores from the above properties, and a combination leaching, concentrating, and smelting method that will give satisfactory results has been decided upon.

When the development of the above mines had progressed to a point where it was deemed prudent to do so, the decision was made to secure title to these properties. The Santiago Mining Co. was organized under the laws of the State of Delaware. The authorized capital \$10,000,000, divided into 400,000 shares of the par value of \$25 each.

The Anaconda company will, from time to time, as it becomes necessary, advance funds for the requirements of the Santiago company, taking its stock at par for such advances. Upon the completion of the financing of the company, Anaconda will own approximately 80% of the issued stock of the Santiago, the remainder will be owned by William Braden and his associates under the contract between them and the Exploration organization of Anaconda. The plan of initial development adopted contemplates the development of Africana to a production of 500 tons of ore per day and of Lo Aguirre to 750 tons. Development of orebodies is being continued, but construction of mining and metallurgical works has been deferred until the resumption of normal conditions.

MOUNT BISCHOFF TIN MINING CO.

Property: mines and mill at Waratah and smelter at Launceston, Tasmania. One of the world's greatest tin mines.

Operating Officials: J. D. Millen, general mine manager; F. B. Jackson, smelter manager.

Financial Statement: for half-year ended December 31, 1917, tin realized \$39,091 (\$191,000). Of this, £12,472 \$60,000) was profit. Balance at June 30 was £88,533 (\$423,000), and end of 1917, £84,284 (\$403,000).

Dividends: £6000 (\$28,800) was distributed, making £2,475,000 (\$11,880,000) to date, equal to \$990 per share.

Development: nearly all work is on the surface. Reserves are 1,250,000 tons of 0.301% (6 lb.) tin ore.

Production: the new mill, aerial trams, power-plant, and smelter are in good order. There was concentrated 52,655 tons, giving 219 tons of concentrate. This yielded 301,461 lb. of 99.87% tin. All costs were \$1.82 per ton.

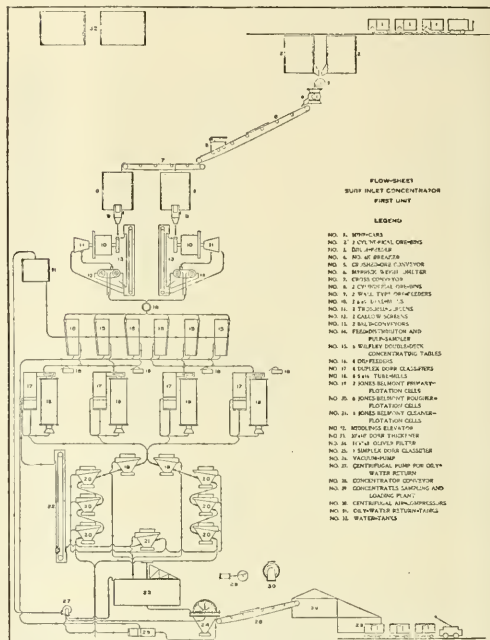

BELMONT SURF INLET MINES, LTD.

Property: gold-silver-copper mines and mill at Surf Inlet, Princess Royal island, British Columbia.

Operating Officials: F. W. Holler, superintendent; H. J. O'Connell, mine superintendent; F. H. Penn, mill superintendent; E. W. Hawkins, auditor.

Financial Statement: from September 1, 1917, to February 28, 1917, the revenue was \$325,792. Operations cost \$239,637, leaving a profit of \$86,154. Current assets total \$326,258, and liabilities \$200,233, including \$168,215 due the Tonopah Belmont company of Nevada.

Development: during the year ended February 28, 1918, there was 3256 ft. of work done, making 12,329 ft. to date. The plant was complete enough to start milling on September 1, but a hurricane on November 2 wrecked the conveyor-bridge which carries ore to the mill from the crushing plant. Most of the development was done between the

FLOW SHEET OF THE MILL AT SURF INLET, BRITISH COLUMBIA

200 and 550-ft. levels. Reserves are in excess of the 385,320 tons estimated on March 1, 1917.

Production: the mill treated 33,207 tons of ore, assaying 0.501 oz. gold, 0.354 oz. silver, and 0.194% copper, valued at \$11.106 per ton. The recovery was 92.09%. Concentrate—2964 tons—contained 15,262 oz. gold, 9870 oz. silver, and 129,138 lb. copper. Costs totaled \$8.433 per ton, which will be lowered during the next year.

Generally the new equipment is working satisfactorily.

PORCUPINE-CROWN MINES CO.

The report of this Porcupine company shows that in 1917 it earned a profit of \$132,448, of which \$120,000 was paid in dividends. The balance on January 1, 1917, was \$277,129, and on December 31, 1917, \$265,206. Development amounted to 2166 ft., also 1260 ft. of drilling, nearly all below the 500-ft. level. No discoveries were made. There is only one shoot at depth instead of two above. Reserves are 600,000 tons, valued at \$610,000. Owing to general conditions it was decided to curtail production, to carry on development only, and to suspend dividends. The mill treated 32,722 tons of \$10.97 ore, of which 97.09% was extracted at a total cost of \$7.07 per ton.

SPELTER production was accelerated in 1916 and 1917 to such a degree as to surfeit the market and exceed consumption, the consequence being an inevitable slump in the price. The logic of events has forced producers to co-operate with a view to regulating production, and this has been done despite the Sherman Antitrust law, with the cognizance of the authorities at Washington, themselves anxious to prevent the further demoralization of the zinc industry. Mr. C. E. Siebenthal, specialist on zinc to the U. S. Geological Survey, has written a letter, approved by the Secretary of the Interior, recommending a discontinuance of production in the lower grades of spelter for several weeks, at least, in order to stiffen the market.

CHUQUICAMATA'S development has been hit hard by the War, which diminished the amount of shipping available for exporting copper and for importing the necessary supplies. The Chile Copper Company, which owns the great mine in Antofagasta, had to raise \$17,665,000 by a bond issue in 1917, bringing the total bonded indebtedness to \$32,665,000, all of which has now been spent. The Guggenheims were clever in keeping the stock and in persuading the public to buy the bonds wherewith to finance the development and equipment of the property. As yet no dividend is in sight, the earnings last year being \$1.43 on the 3,800,000 shares. In 1917 the production was 89,022,126 pounds of copper, at a cost of 13.2 cents per pound, as compared with 10,944,000 pounds at a cost of 18.55 cents per pound in 1915. This suggests what progress has been made in two years, but it is "a long, long way" from the 4-cent copper of promotion days. Even the War cannot be blamed for all of the shortcoming. We appreciate the difficulties of technical men when they are expected to make good the flamboyant predictions of cheerful financiers.

PULVERIZED coal is being tried in the blast-furnace smelting of copper ores at the plant of the Tennessee Copper Company. Full details have not come to hand, but it appears that the firing of the coal-dust is done through alternate tuyeres. The consumption of coal is said to be 3% of the weight of the charge, whereas 6% of coke has been used heretofore in the semi-pyritic practice at Ducktown. The advantages to be gained by employing coal-dust are easy to see. If successful, it

would afford an economy in fuel, it would admit of close regulation of the ratio of fuel to air so as to provide the correct proportion of carbon monoxide needed as a reducing agent, with a correspondingly high temperature at the point where it is most desired; furthermore the gases would be free from unconsumed carbon. At the same time the volume of gases issuing from the furnace would be reduced, thereby proportionally increasing the content of sulphur di-oxide. As a result a cleaner and richer sulphurous gas would be available for use in the sulphuric-acid plant, which is so important an adjunct to the Tennessee Copper Company's smelter. After a trial of two weeks the indications were favorable for overcoming the minor difficulties experienced at first, and the new method may be adopted as routine practice.

'WORK or fight' was the decree that dispelled the blissful dreams of that class of 'tramp' labor from which the ranks of the I. W. W. mostly have been recruited. The great mass of American labor has nothing in common with those pariahs of the industrial world. Now another blow has been struck at the same shiftless sowers of dissension. The 'tramp' worker is only a degree above the hobo; they are varieties of the same species, and are for sale to any dealer in iniquity. Thus, the revelations at Chicago have shown how the I. W. W. were used as an instrument of the most corrupt propaganda ever known to man—the propaganda of German kultur. The 'tramp' disguised as a workman has worn the 'grouch' as his most conspicuous garment; he has disturbed the peace of honest men who labor with their hands to provide homes and loving care for wives and children. It is he, more than any other, that has fought against the right of employers to discharge men from service except under narrow rules established by the labor-unions, while at the same time insisting upon the privilege of asking for his 'time' whenever it might suit his whim, regardless of the gap his sudden departure might create in the ranks of the miners, the millmen, or the factory-hands. The President has now created a war-labor board, and after August 1 the employment and distribution of certain classes of workmen will come under Federal direction. In the view of the Government, the skilled laborer is rightly regarded as a man of responsibility, worthy to be trusted in choosing the best place to use his ability, for the brain receives culture

from the training of the hand; so the new order, by applying only to the unskilled, strikes directly at the root of much of the difficulty that has disturbed the industrial world since the War began. On the acceptance of a working plan for the better stabilization of labor the employer and employee can be drawn into closer sympathy as true coadjutors, and this makes for an economic and spiritual uplift. The two are more nearly related than the world generally has realized.

LET us hope that the maximum punishment enforceable by law will be meted to the Western Union Telegraph Company for its cynical effrontery, as disclosed by the arrest of the men that were caught carrying bundles of telegrams on the trains between New York, Boston, Philadelphia, and Washington. The punishment should fall upon the highest officials cognizant of, and therefore participating in, the offense. The incident comes home to all of us. It is a mean kind of stealing by a public utility corporation operating under special privileges granted on the supposition that it would serve the public honestly. The excuse that owing to the rush of messages the company found it impossible to transmit them by wire is only an added impertinence. If that were so, why did they charge the full rate, instead of charging a cost equal to that of immediate-delivery postage? The excuse is all the more impudent because we in San Francisco remember how at the time of the earthquake-fire the Western Union accepted thousands of telegrams and cablegrams that the company did not transmit by wire, but either threw into the waste-paper basket or forwarded by mail, at a cost of two cents per message as against the dollar or more that it placed in its cash-box. It is a stain on our local press that this flagrant larceny was not exposed relentlessly at that time and that the Western Union was not then deprived of its franchise. Such acts are demoralizing in the extreme to our whole system of public utilities and unless they are punished promptly they create prejudices highly detrimental to the national welfare.

IN this issue we publish the testimony given by Mr. Van. H. Manning, Director of the U. S. Bureau of Mines, before the Committee on Mines and Mining of the House of Representatives on the War Minerals Bill. The position held by Mr. Manning and the confidence of the public in his statements on the subject are such as to make his testimony particularly interesting. After all, the justification—the ample justification—for our national mining industry at this time lies in the immediate and invaluable assistance that it is giving the Government in waging this great war. Mining is essential as never before, and everything that it is doing for the national cause is of the most timely interest. Therefore we need not apologize for giving so much space to Mr. Manning's testimony. Among others invited to attend and testify were Messrs. George Otis Smith, Director of the U. S. Geological Survey; Bernard M. Baruch, chairman of the War Industries Board; William H. Nichols,

of the General Chemical Company; C. K. Leith, chairman of the Committee on Mineral Imports; Bradley Stoughton, secretary of the A. I. M. E.; William Young Westervelt, chairman of the War Minerals Committee; Walter Douglas, president of the American Mining Congress; Joseph W. Richards, chairman of the Iron and Steel Committee; Walter R. Ingalls, editor of the 'Engineering & Mining Journal'; Herbert C. Hoover, Food Administrator; Philip N. Moore, ex-president of the A. I. M. E.; J. F. Callbreath, secretary of the American Mining Congress; F. W. De Wolf, president of the Association of American State Geologists; H. A. Buehler, State Geologist of Missouri; W. O. Hotchkiss, State Geologist of Wisconsin; Harry L. Day, mine-operator in Idaho; D. G. Kerr, vice-president of the U. S. Steel Corporation; Pope Yeatman, of the War Industries Board; and Cornelius F. Kelley, vice-president of the Anaconda Copper Company. In our next issue we shall publish the testimony of Mr. Ingalls, who spoke in opposition to the Bill.

Leasing Mineral Deposits on Indian Lands

The Senate has passed bill No. 385, introduced by Mr. Henry F. Ashurst, of Arizona, throwing open practically all the Indian reservations in the country to prospecting for minerals, and authorizing the location of metalliferous deposits in the same manner as that prescribed under the mining law of 1872. This is similar to a bill passed by the House of Representatives in the last Congress. The Senate bill accordingly may be expected to receive prompt approval by the House, especially as it is a war measure. The chief avowed object is to render available certain large deposits of manganese said to exist on some of the reservations, but it must not be overlooked that the miners of the West have cast jealous eyes upon the Indian lands for many years. Senator Ashurst admitted that many would fear that the bill was merely the poking of "the camel's nose under the tent, and that the animal would get in completely later on." That is what the friends of the Indian are sure to think, and their suspicions are not without justification. Section No. 4 of the bill concedes the right of a locator to obtain from the Secretary of the Interior the privilege "to use during the life of the lease a tract of unoccupied land, not exceeding 80 acres in area, for camp-sites, milling, smelting, and refining works, and for other purposes connected with and necessary to the proper development and use of the deposits." Since no persistence in mining or production, beyond that involved in doing \$100 worth of work per annum on each claim, is required, the way appears easy for certain classes of settlers to effect a permanent occupation. In this respect the rights of the Indians would seem to have been imperfectly safeguarded. Locations are to be made in the manner customary for the acquisition of claims on the public domain, but within a year after posting a location notice the claimant must apply to the Depart-

ment of the Interior for a lease, and thereafter the lessee must pay to the United States, for the benefit of the Indians, in consideration of "the privilege of mining or extracting the mineral deposits, a royalty of not less than 5% of the net value of the output," and an annual rental "of 25 cents per acre for the first calendar year thereafter, 50 cents per acre for the second, third, fourth, and fifth years, respectively, and \$1 per acre" for each succeeding year. The leases are to run for a period of 30 years, with the right of renewal for successive periods of 10 years. Here again an invasion of the rights of the Indians might be possible. Their only recompense would be derived from the royalties paid, and the language of the bill would seem to bear the interpretation that payment shall be made only after the issuance of the lease, while the "mining claims may be located by such citizens (of the United States) in the same manner as mining claims are located under the laws of the United States." The Secretary of the Interior receives no authority to impose regulations applicable prior to the issuance of a lease, from which it will be argued that holders of claims may exploit them for one year free from any restrictions and solely for their own benefit. This is not in conformity with the expressed purpose of the sponsors of the measure, but on the other hand it is evident that the necessity for securing leases immediately after location would have delayed the production of manganese and other minerals for use in making war-material. It would have been easy to have exacted an accounting for minerals shipped prior to the execution of a lease, but no such obligation is written in the bill. Anxiety was shown by numerous senators to play fair with the Indians, and a reluctant consent to the measure was obtained from them on the plea of high emergency, despite some risk of invading the rights conceded to the Nation's wards. Senators Shafroth and Smoot objected to the introduction of the leasing system, when applied to metalliferous deposits, as being wrong in principle, and the bill would have been strenuously resisted on this ground except for the assurance that it was not intended to establish a precedent, and that no other convenient means could be found for remunerating the actual owners of the land.

The bill as originally drawn provided for the payment of a royalty of 5% on the gross value of the ore. That would have proved so heavy a burden that the opportunity afforded for mining on Indian lands would have been limited practically to small rich deposits, such as might be exhausted quickly under the stimulus of exorbitant war-prices. The change to 'net value' indicates that the object is not merely to serve the needs arising from the present conflict but to open the metallic resources of these lands to final and complete development. This means nothing less than the encroachment of modern industry upon the preserves of the aborigines, the growth of towns, the development of water on a scale adequate for mills and smelters and crowding workmen. Under pressure of the wants of large industrial communities, more and more concessions will be demanded

and are sure to be granted. This is the logical result of expansion into undeveloped territory. The rights of those that fail to employ the land productively have always been brushed aside in the march of progress. Sanction for our occupation of the whole continent rests upon that principle; nevertheless it is with regret that we see this harsh political philosophy applied to the petty remnant of the Indian lands at a time when the minds of our people are filled with idealistic social doctrines, preached from the White House, the pulpit, and the platform. It might be well to regard more reverently and more consistently the treaties we had signed with the Indians. Though we shrink from too wide an extension of government ownership, it might have been appropriate to have provided that these particular resources of manganese and platinum, so forcibly cited as an argument for shoving the bill through the Senate, should be developed under the direct control and management of a Government bureau for the pecuniary benefit of the actual owners in law and equity.

The Slump in Gold

In the annual report of the Dome Mines Ltd., in Canada, the manager, Mr. Charles D. Kaeding, refers to the cessation of productive operations and says: "The economic fallacy of operating a gold mine under existing conditions, even were there a sufficient supply of labor, is now so much better understood that it is hardly necessary to point out the decreasing profit per ounce of metal due to the increasing cost of production and the fixed price of this standard. It will not be possible to resume operations until conditions become more favorable." This company closed its mill in December last and is now restricting work to the sinking of its main shaft. Another company, the Canadian Consolidated Mining & Smelting Company, has issued a notice to its employees in British Columbia, stating: "Large increases in the various items entering into the mining and smelting of the Rossland ores, such as wages, cost of explosives, coke, steel, general mine and smelter supplies, without adequate compensation in values by way of increased metal prices, coupled with increased taxation, have made it necessary for the company to suspend shipments from the Rossland mines indefinitely. An endeavor will be made to keep a small force on development work, and to place the remainder of our Rossland employees at the smelter, the Sullivan mine, Kimberley, and other lead-silver properties of the company." The ore produced by the mines at Rossland is a low-grade silicious copper ore valuable chiefly for its gold content. One of the company's officials says: "As a gold dollar will hardly buy half as much as before the War, there appears to be no great advantage in mining gold ores at this time—especially when almost every variety of mining cost has doubled and more." These remarks will find a sympathetic response among gold miners elsewhere. In California it is reported that the shortage of power may compel dis-

crimination in the distribution of electrical energy, and that one of the first industries to suffer will be gold mining on the Mother Lode, on the supposition that it is not among the activities most essential to warfare. We say 'supposition', advisedly, for to us it seems a fallacy to suppose that gold is not an important resource in time of war. "We don't want gold from the mines; we can make money with a printing-press," says the shallow observer, echoing a sentiment that is allowed to grow like an economic weed. Assuredly if the gold miner is to pay a double-price for his material and is to receive a half-price for his product, he will be well advised to cease production until such time as gold is in demand again; and that time is sure to come on the day of reckoning when the paper-credits now so freely issued are brought to account. The terrific slump in the commodity-value of gold is perhaps our best example of the evil effect produced by discriminatory price-fixing. In terms of drill-steel, looking at the matter from the vendor's end, 286 pounds of $\frac{3}{4}$ -inch octagonal steel would buy a shining double eagle in 1912, whereas only 80 pounds are needed now to land the same sum in the steel merchant's bank account. In this case the decrease in the commodity-value of gold has been 72%, or, to state it in terms of steel, the price has risen 257.5%. Compared with copper, the average price of which for many years before the War was 15 cents per pound, 133 $\frac{1}{2}$ pounds would purchase a \$20 gold-piece in 1912, while 85 $\frac{1}{10}$ pounds will capture it today, the corresponding percentages being 36.1 and 56.6. It will be observed that we have compared a finished product with a refined raw product. The quotations on drill-steel, however, are based upon the ingot, the price of which is fixed, while no control is exerted over the manufactured article. The price-ratio between steel ingots in 1912 and at the present time is 2.72, representing a decrease in the purchasing power of gold amounting to 63.3%, much more nearly approximating the relations shown by the prices paid for copper in the two periods. Tungsten is a conspicuous example of the opportunity presented by an uncontrolled industry to advance prices to an abnormal height. Before the War the average quotation was about \$6.50 per unit of WO_3 ; the current quotation is \$24. Using our reversed view of the relation of commodities to money, 3.076 units, or 61.52 pounds, would buy \$20 in 1912, whereas 0.833 unit, or 16.66 pounds will do it today, the purchasing power for gold having augmented 269.2%. Examples might be multiplied to illustrate the truth that price-fixation, when not based on a strictly democratic principle, exposes the restricted industries to extortion by those that are free. Gold has suddenly become altered in its relation to commerce; suddenly it finds itself among the fettered. Formerly it was the arbiter of value. Quantity of merchandise was expressed in terms of a unit-weight of this token-metal. Being the unit of reference it must be considered, for monetary purposes, as having no value in itself. The common fallacy of a superabundant intrinsic value in gold as the thing that determines its use as a monetary standard

grew out of failure to note the fact that it was just because gold was so lacking in adaptability to utilitarian purposes, while at the same time possessed of extreme beauty, density, and resistance to corrosion, that it fulfilled so perfectly the requirements of a token in commodity-exchange. Such a token by its very nature must come as near to typifying an abstract conception of measure as any material thing can do. The yard-stick that measures cotton cloth cannot safely be a piece of cotton cloth, but rather an expanded unit derived from the fundamental conception of the human energy required to produce the three barley-corns that made the inch of our grandsires. The human effort represented in the pleasing and nearly indestructible gold is at the bottom of the idea of the standard for which men will exchange the fruit of their labor. It is human-power, 'man-power' in the phrase of the day, that we exchange with each other, and the gold is the symbol of it, as the cross is the symbol of redemption. What would you do with the gold you receive but exchange it for something else? Would you make yourself a hoe of it, or a sword, or an automobile? Steel would be worth vastly more for any of those purposes. So, while the world crowded the busy marts, buying and selling, as there was need, and doing it in the name of the imperishable and gleaming symbol of labor, gold was the prince over industry. The moment, however, when men no longer may appraise their wares in barter on the sole basis of need, but discover the offspring of some labor bound and that of other labor free, the prince of trade himself, in whose name a value has thus been quoted falsely, becomes a slave among the bondsmen, and is delivered over to the scant mercy of the industries that have not been chained. Moreover, because value is still expressed in terms of gold, you cannot fix its own value at a higher level, for if you do the credits piled to such a dizzy height in representation of services rendered in the past, gauged as they are by this golden measure, will at a single stroke have been blotted from the account to the extent that the arbitrary weight of gold in the dollar may be changed. The basis of industrial confidence would be so shaken by it that the world would experience the calamity of a plunge into commercial and industrial chaos. There is but one way to protect both gold and general industry; and that is to build up the gold reserve faster and faster as a foundation adequate to sustain the growing national indebtedness. That indebtedness means services loaned, but the repayment must be made in currency, the only guarantor of which is the royal metal. The way to reenthroned gold as the arbiter of commercial value is either by crystallizing the prices for all commodities, or by letting all markets regulate themselves on the ancient principle of supply and demand. Half-slave and half-free it is certain that industry, commerce, banking, and insurance, will presently fall into a slough of difficulties from which we may not extricate them before appalling damage will have been inflicted not alone upon the economic life of our own day but upon that of generations to come.

Magazines for the Wounded

The Editor:

Sir—The American Committee of Engineers in London has received a request for copies of American Technical magazines for the use of American hospitals in England, France, and other European countries where such are established. Although many London offices receive regularly the American mining, electrical, railway, mechanical, excavating, and other technical periodicals, there is no regular system of distribution by which such publications can reach wounded officers and soldiers of the American Army. We therefore beg that you will publish this letter in your columns, together with the request that any individuals or companies having spare copies not needed for their files will forward the same either directly, or through the medium of the local Red Cross, to Mrs. Miller, American Red Cross Care Committee, 154 New Bond St., London, W.

C. W. PURINGTON.

Manganese

The Editor:

Sir—The recent fixing of prices on manganese ore by agreement between the American Iron & Steel Institute and the War Industries Board is unfair to Californian producers and will result in a lowering of returns to ore-producers in northern California, and will undoubtedly curtail if not wholly eliminate production. Proposed additional freight-rates are prohibitive.

Prices are now based on deliveries at South Chicago, the freight paid being deducted from returns to the ore-producer. Freights from Pacific Coast points to South Chicago are from 50 to 100% higher than from other producing points. A bonus is given to producers east of Chicago, although their freights are much lower than ours. No reason is announced for this bonus. If any bonus is paid to any producer, surely those paying highest freight-rates are entitled to it.

Smelters on the Pacific Coast, by buying on the Chicago base, will obtain their ores at a lower price than previously prevailing prices. When 80% ferro-manganese was selling at \$250 per ton, we were able to dispose of all our ores at from 16 to 25% higher than we will receive under the fixed prices and now the ferro-manufacturers have had their returns increased by the lowering of the specifications to 70% manganese content with no lowering of the price per ton.

Our ores are nearly all high in silica, low in iron, and low in phosphorus. Although in the past we have sold

our ores on the basis of total free silica and free silica to 20% and the manufacturer has been glad to get them, we are now being penalized on the silica and no allowance made for low iron and low phosphorus. We are paying the highest mining wages in the country in this industry and this is necessary as the mines are new and do not possess the comforts found in the larger mining camps.

So far as we know no producers in Northern California were asked to submit any figures showing what the price fixings would do to his ores. The present output is not large, but, if encouraged, production might become important factor in the national supply.

M. C. SEAGRAVE.

San Francisco, June 17.

Locating Metalliferous Lodes Containing Alunite

The Editor:

Sir—I am writing you for information, and will be thankful if you will answer the following question. I have had the matter up with several persons, and have had a different answer from each of them. A number of us have located mining ground containing gold, silver, sulphur, cinnabar, and alunite. The properties are held in part as a quartz and in part as a placer location. We have performed the location work and have had the claims recorded. The claims were located and the location-work was done in January 1918. The ground containing the silver veins also contains large bodies of alunite and cinnabar. We recently tried to dispose of our holding, and were informed we would have to lease it from the Government, while others affirmed that we could hold it as a quartz claim. We would like to know what we have to do to hold our claims, and to obtain a valid right that can be conveyed. We would also like to know if it is true that the Government has passed a law making it necessary for one to lease ground containing alunite.

J. F. LAW.

Salt Lake City, May 26.

[The mining law of 1872 still holds good as to all minerals not otherwise provided for according to recent acts of Congress. Under its terms a valid lode-claim can be located on any unappropriated public land of the United States, wherever a valuable deposit of gold, silver, cinnabar, or other minerals not excepted by special legislation can be shown to exist. The incidental accompaniment of alunite cannot defeat the right of a discoverer to locate a deposit of gold or silver or other metals when

the quantity present is sufficient to admit of their economic exploitation. We are advised by legal authority that in view of the recent legislation by Congress, applicable to chlorides, sulphates, carbonates, borates, silicates, or nitrates of potassium (Public No. 49, 65th Congress, approved October 2, 1917) a locator of lands containing gold, silver, or other metals, would not, in all probability, acquire the right to mine and dispose of deposits of alunite found in the same located lands. Section 12 of the act above referred to contains the following language: "That the deposits herein referred to, in lands valuable for such minerals, shall be subject to disposition only in the form and manner provided in this Act, except as to valid claims existent at date of the passage of this Act, and thereafter maintained in compliance with the laws under which initiated, which claims may be perfected under such laws." While the Act has not as yet, to our knowledge, been construed by the courts, it seems to be intended to provide specifically for the exploration of lands valuable for potassium deposits, and for the disposition of such deposits. It is to be noted that the Act repeatedly refers to the deposits of potassium rather than to the lands containing them, and it is reasonable to assume that such deposits wherever found in lands not lawfully claimed at the date of the Act, October 2, 1917, become permanently sequestered from the Public Domain, at any rate, where known to exist. Of course, if patent should issue for the mining claims containing gold, silver, or other metals, and deposits of potassium salts should be discovered subsequently, they would most probably be held to be the property of the owner of the patent title.—EDITOR.]

Formulas for Mine Valuation

The Editor:

Sir—In your issue of May 18 appears an article on this subject by W. W. Whitton, in which the author undertakes to show that the old Hoskold formula for calculating the present value of an annuity yielding interest to the investor at one rate, and redeeming the invested capital by means of a sinking-fund earning a lower rate, is in error by as much as 20% when applied to the valuation of a wasting asset such as a mine. The same arguments against the old formula have been brought up from time to time; the first time I remember hearing them was in South Africa in 1904.

The question as to whether the Hoskold method of mine-valuation is in error or not depends upon the definition of 'a 10%' or 'a 6%' or any other rate of investment, for a finite term of years. A 10% investment for a definite period is commonly understood to mean one that will pay the investor 10% interest per annum on the capital invested and return the total amount of the capital at the end of the period. A 7% twenty-year bond, for example, is one that will yield 7% per annum on the par value of the bond, and return the par value at the end of 20 years. The sinking-fund to redeem the bonds is usually provided by the company out of the profits of the business.

Let us consider Mr. Whitton's case of a mine with an expected life of 10 years, paying an annual dividend of \$1000, the rate allowed on the investment to be 10% and on the sinking-fund to be 4% per annum. By the old Hoskold formula the present value of this annual dividend is \$5455.81. Out of each year's dividend \$545.58, or 10% on the investment, is paid as interest and \$454.42 is put into the sinking-fund. At the end of the ten-year period the investor will have received 10% per annum on his investment and his capital back, which fulfills the definition of a 10% investment.

According to Mr. Whitton's proposed method of valuation, the same mine would have a present value of \$6591.37, and the annual dividend would be distributed as shown in the following table:

Year	C	d	CI	d-CI	Amount in sinking fund
1	\$6591.37	\$1000	\$659.14	\$340.86	\$340.86
2	6250.51	1000	625.05	374.95	729.44
3	5861.93	1000	586.19	413.81	1172.42
4	5418.94	1000	541.89	458.11	1677.43
5	4913.93	1000	491.39	508.61	2253.13
6	4338.22	1000	433.82	566.18	2909.44
7	3681.91	1000	368.19	631.81	3657.62
8	2933.72	1000	293.37	706.63	4510.56
9	2080.78	1000	208.08	791.92	5489.90
10	1108.44	1000	110.84	889.16	6591.37
					\$4317.96

The column 'C' shows the amount of capital remaining invested at the beginning of each year, column 'd' the annual dividend, column 'CI' the interest paid to the investor, and column 'd-CI' the amount put into the sinking-fund. The last column gives the total amount in the sinking-fund at the end of each year.

It is immaterial in this discussion whether the mining company or the investor looks after the sinking-fund. It cannot be used for any other purpose than to redeem the capital invested, and therefore cannot be considered free capital to be used for other purposes until the end of the life of the mine. At the end of the life of the mine the investor in this case will have received \$4317.96 in interest and his capital back, or an average of 6.5% per annum.

An investor in mining stocks takes more than the ordinary risk because of the larger return on his money if the mine comes up to expectations. He assumes this risk at the moment of purchasing the shares, before it is certain that the mine will come up to expectations. Would he assume the risk if he knew that, in the event of the mine's fulfilling all expectations, he would only receive a rate of interest which could be had by investing in something much more secure, for instance bonds? He would certainly buy the bonds and avoid the risk.

According to the definition of a 10% investment given above the old method of valuation is not in error.

New York, June 8.

K. F. HOFFMANN.

TAILING dressed by flotation at the Broken Hill Proprietary Co.'s works in New South Wales totaled 3,291,942 tons to the end of November 1917. This yielded 816,734 tons of concentrate. The slime-flotation plant (Bradford process) is making a concentrate carrying 48.79% zinc, 4.81% lead, and 14.80 oz. silver; and 61.62% lead, 8.98% zinc, and 83.25 oz. silver per ton.

The War-Minerals Bill

EVIDENCE OF VAN H. MANNING, DIRECTOR U. S. BUREAU OF MINES

The Committee on Mines and Mining of the House of Representatives, under the chairmanship of Mr. Martin D. Foster, of Illinois, has held a series of meetings during the last three months in order to elicit an expression of opinion from representative men concerning the bill "providing," as the Chairman said, "for the national defence by encouraging the production and conserving the supply of metals and minerals for the needs of the Government." Among those invited to testify was Mr. Van H. Manning, Director of the U. S. Bureau of Mines. His testimony was fortified by a mass of valuable information, which we publish herewith, together with the colloquy between him and members of the Committee.

MR. MANNING: I would like to make a short statement in regard to the importation and uses of minerals of military importance. The Interior Department has prepared an extensive statement on the subject. I think it would be interesting reading to the members of the Committee, and also the House when they have the bill under consideration, and, with your permission, I would like to submit it for the record. [Here follows Exhibit A.]

IMPORTANCE OF MINERALS TO WARFARE

Minerals furnish the most important materials for munitions. The importance of the following minerals is far greater than either their tonnage or value would indicate. The two fundamental materials for the production of all modern high-power explosives are nitrate, chiefly as nitric acid, and concentrated sulphuric acid made from pyrite or sulphur. Manganese is the most essential alloy for high-grade steel for munitions and important industrial uses. Flake graphite is used for crucibles required in the production of brass and crucible steel. Tin is required for tinplate for utensils and cans for preserving food and for bearing-metal. Mercury is used as fulminate to explode cartridges and shells, and is essential for the safe and effective use of all high explosives. Potash is used chiefly for fertilizers with small amounts for explosives, soap, glass, and chemicals. Tungsten is an essential alloy for high-speed tool steel. Antimony is required for hardening lead for bullets. Chrome is used to make an alloy for tool steel and as a refractory lining in basic open-hearth steel furnaces. Magnesite is used as a refractory in metallurgical plants. Mica is indispensable as an insulating material in the manufacture of electric apparatus.

DANGER OF DEPENDENCE ON FOREIGN MATERIALS

Many of the minerals referred to in the bill have been largely imported. Dependence upon foreign sources for mineral supplies may involve the diversion from military service of ship tonnage for the actual import of the min-

erals themselves; for the movement of fuel, equipment, and supplies to the foreign mines producing these minerals, for the possible transportation of other products which the nations upon whom we depend may exact from us in return for their essential minerals. In view of the uncertainty of such supply, as well as the shipping involved, it is essential that domestic production be stimulated to the utmost.

RELEASE OF SHIPS FOR MILITARY PURPOSE

At the present time every ship that can be spared is needed to extend our military operations. The minerals imported come from many distant sources involving long voyages and delays in loading. The minerals mentioned represent an import of about 2,000,000 long tons per year, three-fourths of which at least can be eliminated in case of extreme necessity. Every additional day spent in the submarine zone is dangerous. In addition to the sacrifice of ships the importation of bulky minerals congests our ports and exhausts our credit in the purchase of supplies abroad.

IMPORTANCE OF STIMULATING DOMESTIC PRODUCTION

We have increased our production very slowly, due to many factors which can and must be remedied. Uncertainty as to the length of the war, fear that sudden return of peace will close down the new mines, no effective guarantee of prices for a reasonable time, and difficulty as to securing labor, fuel, and supplies have discouraged the producer.

The consumer has not realized that new production is usually a matter of at least six months' time; he has depended upon the Government to take care of his needs; he has hesitated to use new materials; his efforts have been largely bent toward urging the necessity of import without realizing the seriousness of the shipping situation.

If this country is to be assured of an adequate supply of minerals for any possible contingency of war, constructive stimulation of production must be undertaken without delay. This should include not only imported minerals which we can largely produce at home, but in addition those minerals which we now produce at home but whose production may have to be increased as our military requirements expand.

IMPORTANT USES AND SUPPLY OF SPECIAL MINERALS

ANTIMONY is used as an alloy of lead to harden bullets for small arms and shrapnel, as an alloy, in type metal for printing, and in bearing-metals used to lessen friction. About 23,000 long tons of metal were required in 1917. Over 21,000 tons were imported, two-thirds of which came from China and the rest from Bolivia and Mexico. The principal domestic sources of ore contain-

ing antimony are in Nevada, California, Idaho, Washington, and Alaska.

ARSENIC. The most important uses of arsenic are for insecticides and weed-killing compounds, disinfecting, vermin poison, and in glass making. The 1917 requirement was about 10,000 short tons, 40% of which was imported from Mexico and Canada. The United States production comes almost entirely as a by-product from smelters.

BALL CLAY—KAOLIN—PAPER CLAY. Ball clay is a white-burning clay used by potters to give plasticity to their mixtures. Kaolin is a white-burning clay employed chiefly in the manufacture of white earthenware and porcelain. Paper clay is any fine-grain clay of proper color that can be used as a filler in the manufacture of paper. Kaolin is the clay most commonly used for this purpose. Kaolin and ball clay are required in the manufacture of the better grades of pottery, sanitary ware, tiles, and porcelain for electric insulation. In 1917 about 260,000 long tons of these clays were imported, chiefly from England. If the import of these clays is discontinued, due to the scarcity of shipping, steps must be taken to further stimulate the production of properly prepared grades of domestic clays. Deposits of ball-clay are found in Kentucky, Tennessee, Missouri, Florida, and New Jersey; of kaolin in North Carolina, Pennsylvania, Alabama, Georgia, South Carolina, Connecticut, Maryland, and Virginia.

BISMUTH. The various salts of bismuth are largely used in medicine, particularly for the dressing of wounds, and a small amount is used in type metal. The total amount used is small. Under normal conditions about 100 short tons was imported, but this import has greatly declined since the War. The chief source of domestic supply is from the electrolytic refining of lead bullion and flue dust.

BROMINE is important because of its uses in medicine, chemicals, and war gases. The total quantity used is relatively small. The United States production in 1917 was 450 tons. It is produced in connection with the manufacture of salt from natural brines from Michigan, Ohio, and West Virginia.

CERIUM. Salts of cerium are used in the manufacture of aniline black, in a number of inorganic compounds, in photography, and in medicine to a small extent. Its use has been suggested for the ignition of explosives and as an illuminant in military signaling. Cerium is contained in the residues obtained from monazite in the extraction of thorium. No figures of production have been compiled, but in the past the available supply has greatly exceeded consumption.

CHALK. A great deal of crude chalk has been formerly imported from Europe due to cheap ballast-rates. In 1917, 130,000 long tons were so imported. It is largely used in the manufacture of whiting which is used as the basis of white-wash, to mix with other pigments, and for putty. In case the shipping situation makes necessary the discontinuance of this import, steps must be taken to secure suitable domestic material or substitutes to replace it.

CHROMITE is used as the alloy ferro-chromium in the manufacture of special steels for high-speed tools, of automobile axles and springs, locomotive frames and springs, certain parts of ore-crushing apparatus, in projectiles, armor plate, and cannon linings. It is also used as a refractory lining for metallurgical furnaces, and its various salts are used in special leather-tanning processes and for chemical colors and dyes. In 1917 the domestic production is estimated at about 42,000 long tons and the import at 72,000 long tons, making a total supply of 114,000 long tons, which is a falling off of about 50,000 tons as compared with 1916. The import comes principally from Rhodesia and New Caledonia. The domestic production has come principally from California and Oregon.

COBALT is used as an alloy in the manufacture of high-speed tool steels and also used in coloring glass and ceramic wares. A new alloy called stellite, consisting of chromium and cobalt, possesses properties which make it a most desirable tool steel. The increased demand for cobalt may probably be traced to this alloy. The United States production of cobalt in the past has been negligible. One or more deposits containing cobalt are now in course of development. The principal source of supply is Canada, and imports of cobalt and cobalt ores in 1917 amounted to 100 long tons. The most important domestic deposits are in Missouri and Idaho.

CORUNDUM AND EMERY are the two most important natural abrasives which have been imported. They are necessary for the grinding of optical glass and special grades of steel for munitions. The best grade of imported emery comes from Greece (Naxos) and corundum from India and Canada. New York is the principal source of domestic emery and North Carolina of corundum. The production in 1917 was 16,000 short tons and the imports about 2000 tons.

FERRO-SILICON is an alloy of iron and silicon which is made in the electric furnace. It is used to deoxidize steel and in the manufacture of non-corrosive cast-iron used in chemical plants, particularly those which made acids.

FLUORSPAR. The principal use of fluorspar is as a flux in the manufacture of open-heat steel. In addition, it is used in the metallurgy of aluminum, copper, antimony, and lead, and in the manufacture of hydrofluoric acid. The United States production has increased since the War to 156,000 short tons in 1916, while the import from England has dropped off to about 10,000 tons. The United States production comes principally from Illinois and Kentucky.

FULLER'S EARTH finds its chief use in the bleaching, clarifying, or filtering of fats, greases, and oils, particularly in the refining of petroleum. The United States production has increased largely since the War to 68,000 short tons in 1916, while the import has decreased somewhat to about 15,000 tons. Three-fourths of the domestic production comes from Florida, with Georgia as the second State in importance.

GRAPHITE is an important war material because of its use in the manufacture of crucibles required in the pro-

duction of brass, bronze, crucible steel, and various other alloys and metals. Only the flake form is used for this purpose. The amorphous form is less important and is used for foundry facings, paint, lubricants, and lead pencils. In 1917 the domestic production was approximately 3400 tons of flake graphite and the foreign import about 27,500 tons, making a total supply of about 31,000 tons. The import comes chiefly from Ceylon and Madagascar, the domestic production from Alabama, Pennsylvania, and New York.

GRINDING PEBBLES. Flint pebbles imported from Europe are used for grinding cement clinker, ores, minerals, etc., and are also themselves ground for use in pottery. Imported pebbles are generally superior to the domestic grade, but since the beginning of the War domestic material has been more widely used. The domestic production in 1917 was 19,000 tons, and imports amounted to approximately 10,000 tons. The domestic output, largely in the form of natural beach pebbles, comes from California.

IRIDIUM is a metal closely associated with platinum and is used as an alloy to harden platinum for use in contact points for magnetos. The quantity used is very small, but is absolutely essential. Shortage of this metal would be even more serious than a shortage of platinum.

MAGNESITE when calcined at high temperature produces a very dense fire resistant and chemically inactive substance. Its use is chiefly for refractory bricks, as linings for open-hearth steel furnaces, copper converters, reverberatories, electric, and other furnaces. In 1913, 185,000 short tons of magnesite were imported, chiefly from Austria and a small domestic production came from California. New deposits were discovered in the State of Washington, and at the present time the product from California and Washington meets our requirements.

MANGANESE is used as an alloy in the manufacture of the greater portion of our high-grade steel. A very small quantity is used in dry batteries, glass manufacture, and dyes. Manganese is the best-known material to produce a dense homogeneous steel free from honey-combing and blow-holes. It is generally added in the form of an alloy of manganese and iron, the high-grade material being known as ferro-manganese and the low-grade material as spiegeleisen. At the present time, steel industry requirements are from 700,000 to 800,000 long tons per year of high-grade ore, besides a large quantity of lower grade ores. In 1917 over 500,000 tons were imported from Brazil, 50,000 tons from India, and about 60,000 tons from the West Indies, and Central America. The domestic production of high-grade ore was 114,000 tons. The principal producing districts for high-grade ore are Montana, Arizona, California, Arkansas, Virginia, Georgia, Utah, and Tennessee. Large quantities of low-grade ore come from Minnesota, Colorado, New Mexico, and New Jersey. There are many small scattered deposits and the possibilities for large increase in production is very good.

MERCURY. The most important use for mercury is in the manufacture of fulminate for use in caps to explode shells, cartridges, blasting charges, and mines. It is thus

essential for the safe and effective use of high explosives for both war and peace purposes. Other uses are in paint to prevent the fouling of ships' bottoms, in the amalgamation process for the recovery of gold and silver, in drugs and for scientific apparatus. The consumption of mercury in the United States is now between 1,750,000 and 2,000,000 pounds. While there has been normally some imported from Spain and Italy, the United States has also exported mercury. The principal mercury producers are California, Texas, and Nevada. The domestic production in 1917 was 36,000 flasks, the imports 5200 flasks, and the exports 11,200 flasks, of 75 pounds each.

MICA. Sheet mica finds its most important use as an insulating material in the manufacture of electrical apparatus such as magnetos, spark plugs, electric-light sockets, etc. It is also used in the condensers of nearly all wireless outfits. The total quantity used is from 1000 to 2000 tons. Imports come chiefly from India and Canada. The domestic production is largely from North Carolina and New Hampshire.

MOLYBDENUM is used as an alloy of steel in the manufacture of high-speed tools, and for automobile parts. It serves many of the same purposes as tungsten and is used abroad more extensively than in this country. The total world output is only a few hundred tons, the United States being the largest producer with about 175 tons of molybdenum in 1917. There are numerous deposits in the western United States whose production could be considerably increased.

OSMIUM is one of the metals associated with platinum. At the present time it is little used, but may become important as a possible substitute for iridium as an alloy to harden platinum.

PALLADIUM is one of the members of the platinum group of metals. Alloys of palladium with gold or silver have recently been devised which furnish a satisfactory substitute for platinum in chemical ware and electric contact and spark apparatus for internal-combustion engines. Palladium is also used for dental purposes. The metal is recovered in the process of electrolytic refining of copper. Deposits containing appreciable quantities of palladium are known in Wyoming and Nevada.

PLATINUM. The importance of platinum lies in its use as a contact material necessary to promote certain chemical reactions in the manufacture of concentrated sulphuric acid and in the production of nitric acid from ammonia. Platinum is used for utensils in chemical laboratories, for contacts in electric apparatus, for jewelry, and for dental work. For all these uses 120,000 ounces is normally required. The domestic production will supply only a few thousand ounces, coming from California and Oregon. The import has been obtained largely from Russia, with a lesser amount from Colombia. Russia is now a very uncertain source, and Colombia, while increasing, cannot meet the deficiency.

POTASH. Before the War we imported over a million tons per year of potash salts from Germany. Over 90% of this material was used for fertilizer, and the remainder was used for various chemicals concerned with the pro-

duction of explosives, soaps, matches, glass, dyes, and tanning. The import has, of course, been entirely cut off, except a small amount from India, and the domestic production in 1917 was only about 12% of normal requirements. A large part of this production has come from old lake deposits in California and Nebraska and as a by-product recovered from cement plants. A great many new processes are being developed for the recovery of potash from alunite, feldspar, marl, and various organic waste materials such as molasses, wood ashes, and wood scourings.

PYRITE is a mineral containing iron and sulphur. It is used chiefly in the manufacture of sulphuric acid. The pyrite when roasted produces a sulphur gas which by various chemical processes finally is manufactured into acid. In 1917 about a million and a half tons of pyrite were available for consumption, one-half of which came from Spain and the remainder from the United States and Canada. A decline in Spanish import has been replaced by an increased domestic production, an increased import from Canada, and a part substitution of sulphur. The principal States producing pyrite are Virginia, California, and New York. New deposits of great promise are being developed in Georgia, Alabama, Missouri, and several other Eastern States. A large amount of this material could be secured as a by-product from coal mines in the Middle West.

RADIUM finds its most important use in the treatment of abnormal growths and cancers. It has been found beneficial in reducing hard abnormal growths of scar tissue which follow some wounds and has possibilities of being still further used for the healing of wounds. It is finding extended use in luminous paints, for compasses, watches, and other instruments used by aviators and mariners. The United States has the largest supply of radium-bearing ores known, although this supply is very limited. The production in 1916 was between 8 and 10 grammes, chiefly from Colorado ores.

SEA-SALT has been used particularly in the preserving of fish, for which purpose it is superior to other salts which are produced in the United States. The import of salt into the United States in 1917 was 66,000 short tons, compared to about twice that amount in 1916. This import was largely sea-salt brought from Mediterranean countries.

SULPHUR has several very important uses, particularly for the manufacture of sulphuric acid for munitions and fertilizers, in the production of wood pulp, as a spray for fruit trees, vulcanizing rubber, and for many other essential chemical purposes. Sulphur has furnished material for an enormous expansion in the production of sulphuric acid for munitions. Formerly almost no sulphur was used for this purpose. The United States is at the present time the largest producer of sulphur in the world. The normal production before the War was about 300,000 long tons, which has since increased several fold. A small import has come from Japan. The domestic production is principally from Louisiana and Texas.

THORIUM. The nitrate of thorium is used in the manu-

facture of incandescent gas mantles. Thorium compounds form a portion of some magnesium flash-light powders. Monazite sand furnishes the crude material from which thorium salts have been obtained. The imports of monazite sand in 1916 were 1100 long tons and domestic production amounted to 17 long tons. The total imports in 1917 increased to 2050 long tons. The principal sources of foreign supply are Brazil and India. The principal deposits in this country are in North Carolina, South Carolina, Idaho, and Florida.

TIN is essential in the composition of bronze and for tin plate used in the manufacture of food containers and many utensils. There is practically no production of tin in the United States, although a very small amount comes from Alaska. The United States is importing about 70,000 short tons of tin per year, chiefly from the Straits Settlements and Bolivia. An increased amount of tin ore is being imported from Bolivia for smelting in the United States. In addition to the supply of new tin, a considerable quantity of this metal is recovered from scrap.

TITANIUM is used in small quantities in cast iron and steel as a purifier, deoxidizer, etc., for increasing the strength and hardness. Salts of titanium are employed as mordants in the dyeing of leather and textiles. The metal may have certain military applications. Titanium is recovered from the minerals rutile and ilmenite. Deposits of rutile are found in any States. Ilmenite is also widely distributed, the most important occurrences being in New York, North Carolina, Texas, and Virginia.

TUNGSTEN is one of the most important alloys for high-speed tool steel, and it is estimated that 99% is so used. Tools made from tungsten steel retain their cutting edge much longer and hold their temper at greater heats and therefore permit much more rapid and continuous operation. Small quantities of tungsten are used in electric-light filaments and in electric contacts. The supply of 60% concentrates is between 8000 and 9000 tons, about half of which is imported and the other half produced in the United States. The larger part of the import comes from South America. The domestic production is chiefly from California and Colorado. Smaller amounts come from other Western States.

URANIUM AND VANADIUM. Vanadium is an important alloy used in tool steel and in cast steel where special toughness is desired, as in locomotive frames and parts of automobiles. The total amount of vanadium used in the United States is only a few thousand tons, largely imported from Peru. The United States has a considerable production from Colorado and Utah. If necessary, much more could be produced from other Western States. Uranium has possibilities for use in tool steel, but thus far it has been little used. The United States has very large deposits in Colorado and Utah.

ZIRCONIUM. The chief use of zirconium mineral at present is as a refractory material. Certain alloys have been devised which are said to be particularly suited for armor plates, projectiles, and high-speed machine tools. Among less important uses of its salts are X-ray photography and lighting purposes. During recent years this country has produced no zirconium minerals. The best-

JUNEAU, ALASKA. GASTINEAU CHANNEL; ACROSS IS DOUGLAS ISLAND, WITH TREADWELL

known deposits in the United States are in North Carolina and Florida. The principal foreign source is Brazil.

Mr. DENISON: Is there anything in this document that ought not to be published?

Mr. MANNING: No sir. I think this statement (Exhibit A) will enable the committee to answer any questions that might come up on the floor of the House as to what these minerals are used for and amount imported, and amount of domestic production. I submit another statement (Exhibit B) as to the quantity and value of minerals imported during 1917 aggregating \$177,850,000, and the additional value of domestic production \$120,000,000, making a total of \$297,850,000. The minerals to be controlled are manganese, pyrites, tin, antimony, arsenic, bismuth, bromine, chromium, corundum, emery, graphite, iridium, magnesite, mercury, mica, molybdenum, osmium, platinum, potash, sulphur, tungsten, uranium, and vanadium.

Exhibit B

Quantity and value of certain imported war minerals in 1917

Mineral	Quantity	Value
Manganese, long tons.....	750,000	\$37,500,000
Pyrites, long tons.....	1,000,000	12,000,000
Graphite, pounds.....	48,000,000	12,000,000
Tin, short tons.....	80,000	96,000,000
Antimony, long tons.....	21,600	9,500,000
Chromite, long tons.....	72,000	3,600,000
Tungsten, long tons.....	4,500	6,000,000
Mica.....		1,250,000

Total value of imports.....\$177,850,000
Additional value of domestic production.....120,000,000

Total.....\$297,850,000

Note: The above estimates represent only the value of the imported materials. The additional value of the products of the domestic industries of manganese, pyrites, sulphur, sulphuric acid, graphite, tin, mercury, potash, tungsten, antimony, chromite, magnesite, mica, is approximately \$120,000,000. Thus making a total mineral value involved of approximately \$300,000,000. Sulphuric acid and mercury are not imported to any great extent. Normally over 1,000,000 tons of potash were imported, with a value of over \$20,000,000. Since the War this import has been entirely cut off. Before the War 170,000 tons of magnesite were imported from Austria with a value of about \$2,500,000. This import has entirely stopped.

Only one or two States haven't any of these minerals. Take Indiana, Illinois, and Ohio, for example, they have what are called "coal-brasses", and the sulphur content of a ton of coal-brasses* is more valuable today than a ton of coal itself.

Mr. W. FRANK JAMES: In Michigan what have they?

Mr. MANNING: They have bromine.

Mr. EDWARD E. DENISON: Dr. Manning, in the mines of Illinois, particularly in certain sections down in the southern part of the State, there are some mines that have always been troubled, as they call it, with a great deal of this hard sulphur stuff that they throw out. Can't that be utilized?

Mr. MANNING: That is what the Bureau of Mines started propaganda on several months ago, but the great difficulty was to get the sulphur separated from the coal because of market conditions. They claim they couldn't get the market for the sulphur and therefore they didn't want to separate the sulphur from the coal if they couldn't dispose of it.

Mr. DENISON: This will help you find a market for that?

Mr. MANNING: No question of it.

Mr. MEYER LONDON: Every one of the minerals, I suppose, has a commercial value?

Mr. MANNING: Yes, sir.

Mr. LONDON: And development of them would be of value to the country years hereafter?

Mr. MANNING: Yes.

Mr. LONDON: Wouldn't patriotic conferences with the chiefs of the departments largely cure this lack of co-ordination?

Mr. MANNING: We have had such conferences from time to time and I want to go on record in saying that my relations with every branch of the Government service is as cordial as can possibly be. The War Department has given generous co-operation to the Bureau of Mines and has given us large sums for work that they did not have the facilities for doing, realizing we had the nucleus of an organization to build upon. The Bureau of Mines has increased its personnel from 470 men this time last year to about 1700 men now. Of course, these are new departures; the War Department had not undertaken any of this work before. The character of this work is confidential.

I may say, Mr. Chairman, that I haven't found anyone who is opposed to the principles of this bill. I have found opposition among some sources to the inclusion in a bill of this sort of iron, steel, copper, lead, and zinc. This bill, I am sure, you gentlemen are more familiar with than those of us who drew it, because by careful comparison with the Lever bill you will find it almost follows it word for word. We took that bill because we knew the Lever bill had gone through the mills of Congress, and this provides for the mining industry what Congress has done through the Lever bill for the agricultural industry. In my opinion the successful termination of the War depends as much upon the mining industry as it does upon agriculture.

Mr. LONDON: These five industries you mentioned—iron, steel, lead, zinc, and copper—are they as essential as these other materials?

Mr. MANNING: Yes, sir; I will give you an instance of the Brazil manganese importations. The Brazil imports amount to over 500,000 long tons a year, valued at \$25,000,000. The holdings are by the large corporations, and if the Shipping Board takes off a number of vessels from this trade, it means that domestic manganese ore must be substituted to make up the deficit. Under the licensing you gentlemen were inquiring about yesterday, the President would promulgate regulations providing for the distribution of this supply so as to put it in the hands of other manufacturers so that they would be provided with high-grade manganese until it could be obtained from other sources. The Shipping Board will reduce the pyrites imports from Spain this year to the following amounts:

	Long tons		Long tons
April.....	40,000	August.....	10,000
May.....	30,000	September.....	10,000
June.....	20,000		
July.....	15,000	Total.....	125,000

You must create in this bill a zoning system so as to con-

*Iron pyrite. Editor.

control the distribution of these ores in the nearest territory. In the case of pyrites, that may mean the conversion of pyrite-furnaces to burn sulphur. One of the largest sulphur mines we have in the United States is within 3 or 4 miles from the Gulf coast. One shot from a submarine could put it out of business. There are only two sulphur mines in the United States that are producing, and the maximum production is estimated to be about 3500 tons per day. Our estimated requirement of sulphuric acid is between eight and nine million tons a year, and we are producing seven to eight million tons a year, which means that we must find a million more tons of sulphuric acid, which goes into the agricultural and mining industries, into explosives, and into gas which we must have in very large quantities.

THE CHAIRMAN: Is that consumption likely to increase?

MR. MANNING: It will increase.

THE CHAIRMAN: So that we are compelled to develop these necessities in this country or get them from some other country?

MR. MANNING: Yes, sir.

MR. COURTNEY W. HAMLIN: Has the Bureau of Mines located any other sulphur mines than those you have just mentioned?

MR. MANNING: One just south of Freeport, down near Matagorda, Texas. Recently priority orders have been issued to a company to enable them to get their machinery to their property, which is very promising, and they are on record as saying to me and to the department that they could produce in the course of the next 8 or 10 months, some four or five hundred tons per day. The smelter companies in the United States can produce a very large quantity of sulphuric acid. They don't want to invest several million dollars to put in acid plants to conserve the sulphur going up in smoke at the rate of hundreds and hundreds of tons a day, because there is no price fixed on sulphur or acid, and there is no guarantee given them that if they put their money into it they will get it out. They are perfectly willing to do it under reasonable circumstances.

THE CHAIRMAN: We have the material here if we arrange to utilize it?

MR. MANNING: Yes, sir.

THE CHAIRMAN: What progress is being made in the coke-oven industry?

MR. MANNING: I understand the manufacturers of by-products of coke have contracted for the products of coke-ovens for two or three years in advance.

THE CHAIRMAN: Will they increase the production of these by-products?

MR. MANNING: Yes, sir.

MR. JAMES: Is this bill broad enough to take up every industry that you wish to take care of?

MR. MANNING: Practically. I would like to have seen the entire industry. That is rank heresy before some of these gentlemen here, I guess. As you know, a bill has been introduced by Senator Pomerene to control the iron and steel industries. I feel we should not take too many

bites at a cherry, and if you are going to do it you should get them all in.

MR. JAMES: I represent a district composed of coal and iron industries. I don't know how the people feel about it; I don't care; so far as the War is concerned I am willing now to vote for it to take care of the copper and iron industries, or later on, if that matter comes up, I would like to know whether you think we ought to confine ourselves as a war measure to this?

MR. MANNING: It will appeal to the public and Congress that when you build ships you should control everything that will contribute to it.

MR. MAHLON M. GARLAND: Can't you now control iron and steel?

MR. MANNING: That is now being done through the War and Navy Departments for Government purchases. Mr. Baruch of the War Industries Board has called the companies representing this industry together and they have agreed upon a price to the Army and Navy only.

MR. GARLAND: And they can commandeer the entire output?

MR. MANNING: Yes, sir; so I understand. I don't think that is necessary, however, because I think the iron and steel and copper people are just as patriotic a class of people as you find anywhere in the world.

MR. GARLAND: Why exclude them in this bill?

MR. MANNING: Because legislation controlling the iron and steel industries was on the way even before we undertook to frame this bill; representing the Bureau of Mines, I didn't want the iron and steel industries administered without some control over other industries. I didn't think the prices should be fixed without taking into consideration other commodities that are used to produce iron and steel. You can't fix a price on one commodity without taking into consideration everything that goes to make up that commodity.

MR. OTIS WINGO: My attention has been attracted to the wording of the bill, "to assure an adequate supply, equitable distribution, and to facilitate the production and movement of necessities which in this act shall include ores, minerals, and metals, as follows:" Has your counsel advised you that the language used will limit the terms of this bill to the items named?

MR. MANNING: As the bill is drawn it limits it to minerals specially mentioned in the bill.

MR. WINGO: I know the object of the framers of this bill was to limit the definition of the word "necessaries" to the particular "necessaries" named in this bill.

MR. MANNING: We wanted it limited to the particular "necessaries" named in the bill.

MR. WINGO: That is the reason I wanted your viewpoint. There would be no objection on your part to clarifying that language so that the word "necessaries" should be interpreted to mean anything except the words specifically named.

MR. MANNING: Secretary Lane, in reporting on this bill to the chairman, suggested that, beginning on page 2, line 1, after the word "necessaries", it be amended to read as follows:

Which in this act shall include all ores, minerals, and immediate metallurgical products, metals, alloys, and chemical compounds of antimony, arsenic, bismuth, bromine, chromium, corundum, emery, graphite, iridium, manganese, mercury, mica, molybdenum, osmium, platinum, potash, pyrites, sulphur, tin, tungsten, uranium, vanadium, and of other rare or unusual elements the supply of which may, in the judgment of the President, be inadequate for war and industrial needs.

MR. WINGO: But his suggestion in here would still leave the uncertainty that arises in my mind.

MR. MANNING: I see the point.

MR. WINGO: Without committing myself to this particular language, I want to get your viewpoint if it is intended to give you authority to determine what are necessities?

MR. MANNING: It does not. It is specific phraseology here.

MR. WINGO: We have got men there in Congress as patriotic as you and I, but men who are careful to do things only that are necessary. They would say, "Why not name those things 'necessary' in this act which shall include?"—I haven't run it down, but I am afraid from a legal standpoint we haven't named these so as to include ores, and further over here, instead of saying "necessaries named in this act" we say "necessaries". They would say that included potatoes and wheat and rye. As I understand, it is not your desire to get power to do those things, but your desire is to get those necessities named specifically here, and you wouldn't regard it as antagonistic if that language was made clear, so that the act would include only the items covered by your description here.

MR. MANNING: No objection whatever.

MR. WINGO: You catch the idea I am driving at. Some people might be afraid it would be used to reach out. Especially is that true in the Senate, because one gentleman boasted that the food bill by interpretation, which was contrary to the interpretation the House and Senate and the lawyers put on it, that by reaching out would do things that Congress did not intend should be done. One gentleman made the statement in New York in a speech, which caused a good deal of criticism on the floor of the Senate.

MR. MANNING: I would like to call attention to a letter received by the Secretary of the Interior from the western secretary, Mr. John T. Burns, of the American Mining Congress, which passed certain resolutions. One of the resolutions read as follows:

"Therefore be it resolved, that we favor the encouragement by subsidy, direct and indirect, and in every other way of the production of such rare materials."

And in the preceding paragraph there is mentioned molybdenum and pyrite, etc. Those gentlemen represent mining interests in Nevada, Colorado, Utah, Wyoming, and Montana. We tried to canvass the field to see if there were any serious opposition to this measure, and I found none, except, as I said a while ago, to include all minerals and metals in the operation of this bill.

MR. DENISON: You understand, I presume, under this bill the Government is authorized to take hold of these mines and operate them as Government plants, do you?

MR. MANNING: Mr. Denison, I would rather not answer that question. I would not like to go on record regarding Government ownership, because that is a problem you gentlemen will have to deal with.

MR. DENISON: Do you understand that to be included in this bill?

MR. MANNING: I say that is not contemplated here except in cases of dire necessity.

THE CHAIRMAN: Now, for instance, if a mine should be in litigation and it was essential that the mine should be working for the success of the War, if that mine was closed down and was being kept closed down, the Government ought to have the right to say that that mine must be opened, and if necessary to see that it is opened.

MR. MANNING: That is the point.

MR. JAMES: Suppose a man was not inclined to help the country out of pro-German proclivities, and did not want to operate his mine. Why shouldn't the Government have the right to go in there and operate his mine even if it is Government ownership? Don't you think your bill ought to have that right?

MR. MANNING: Yes, sir.

MR. HAMLIN: We have given the Government that authority in other things to take hold of any factory or anything else needed for the prosecution of this War, and operate them if necessary.

THE CHAIRMAN: That would be only a repetition in this Act.

MR. MANNING: Isn't it true that that only applies to the Secretary of the Navy and the Secretary of War for products for munition purposes? What are you going to do with the domestic consumption?

MR. WINGO: Take the railroad proposition. It authorized the President to take the railroads over and operate them under the Secretary of War and he eliminated the Secretary of War and put it in the hands of the Director General of Railroads. He could name you just like he named McAdoo, is my idea about it, for Army and Navy use only.

MR. MANNING: That is it. For use of the Army and Navy only.

MR. EVERETT SANDERS: Section 12 provides that whenever the President shall find it essential to the successful prosecution of the War to secure an adequate supply of necessities he is authorized to requisition and take over for use or operation of the Government, and so on.

MR. LONDON: If you read a few lines below you will see he is authorized to take the undeveloped or idle lands or mines.

MR. JAMES: Suppose a man has a mine, he is only working 10% of its capacity because he does not want to help this Government, not very enthusiastic for the War really pro-German, when he was working 10% capacity, and he ought to be working 100% capacity, I don't consider this language adequate because that would not be considered an idle mine, it ought to be broad enough to

take over plants of that kind. Do you figure this language is broad enough? It says "idle" although it might be working 10 or 25%.

MR. MANNING: It ought to be classed as an undeveloped mine.

MR. JAMES: It wouldn't be undeveloped.

MR. MANNING: I think a provision of that sort ought to be inserted to have the mine worked to full capacity.

MR. NATHAN L. STRONG: Did I understand you to say the sulphur in the coal is more valuable than the coal itself?

MR. MANNING: At present; yes, sir.

MR. STRONG: I was interested in that. There is one vein of coal in my district with such a high percent of sulphur it is known as the Sulphur vein.

MR. MANNING: A good deal of it has sulphur.

MR. STRONG: It comes out in great slabs.

MR. MANNING: Yes, sir.

MR. SANDERS: I had a man in my office to tell me that he got more for his sulphur than for his coal. That was in peace times—two and a half years ago.

MR. MANNING: I would like to explain the provisions of Section 14 of this bill. This section provides that duties may be placed upon the import of necessities sufficient to bring the price of the imported article up to the same level as any guaranteed minimum price which may be established under this bill. This provision is put in the bill solely for the purpose of protecting the United States government. The Government having once established a guaranteed minimum price must, to make it effective, purchase such ores as are offered it at that price, for the period of the guaranty, which may be two years. In case of a sudden ending of the War, or an improvement of the shipping situation which would permit import, foreign necessities might be imported at lower prices, unless this provision were made, thereby compelling the Government to purchase all domestic material at the higher guaranteed prices and increasing the liability of the Government to this extent.

MR. HAMLIN: That same provision was put in the agricultural bill or a similar one.

MR. MANNING: Yes, sir; we followed very closely the agricultural bill in framing this.

MR. JAMES: When the powder bill was up, you remember, this language "accept the services of any person without compensation", and then a little further, "any person may be employed under the provisions of this act without reference to civil-service laws and regulations." I believe in civil service. At that time you stated it was not the intention of giving Democrats or anybody else a job but simply to take care of a good many men who wouldn't want to take any civil-service examination whatever. You wanted to use them without getting their services for nothing, and at the same time you wanted to take care of that.

MR. MANNING: I will give you a concrete illustration. In the explosion at Jersey City, instead of our bureau sending an expert, Mr. Topping, who was Director of the Bureau of Explosives, a bureau that is organized and

financed by the railroads of the country, went there. He is getting a dollar a year. He made a prompt report to the Bureau of Mines as to the causes of that explosion. We had to give him a dollar a year so as to give him entry to the manufactories and all plants where explosions occur.

MR. JAMES: And this bill today was not for the purpose of the civil service, but using them any way you could get them?

MR. MANNING: I will say for the Civil Service Commission that they joined in a request to the President to remove all war work the Bureau of Mines is doing from the provisions of the civil service. We use the civil service just as far as possible, but we are up against a hard proposition to find employees for the Government today.

MR. JAMES: The last time we had a hard fight on. We had a hard time working it up and your statement saved it.

MR. MANNING: I see no objection to taking the civil service provision out of there. They realize that we are at war, gentlemen, and they are willing to do their part.

MR. WINGO: In other words, there is very full co-operation between the civil service and all the departments so that war work will not be hampered?

MR. MANNING: I can say that if you take the civil-service bars down when the War is over it may be disrupted.

MR. WINGO: They realize the necessity of taking the civil service from certain departments to get men who can do the work.

MR. MANNING: Yes.

MR. GARLAND: Have you made a statement there anywhere in print showing the source of the different articles—what manufactures they go into, for instance? Do a large number of them go into steel?

MR. MANNING: Yes; I have covered that in a former statement.

MR. SANDERS: You think the provision in Section 2, which authorized the President to delegate any authority under this act—

MR. MANNING: One main controller.

MR. SANDERS: Section 2, line 22, the provision authorizes the President to delegate any of his authority under this act to any agent or agencies.

MR. MANNING: He would be compelled to delegate his authority because he is too busy with many matters and would have to delegate authority to somebody to draw up the regulations to carry out the provisions of this act.

MR. ANDERSON: I understand that. Of course, a great many things the President does he must do through agencies, but it really gets his approval in the end and when it has his approval in the end it is considered his act and not a delegation of authority to some one else to do it. Under that there is a provision authorizing the President to delegate that authority to anybody else to make the regulations that he should desire?

MR. MANNING: That might be modified in this way: Of course, you can't say beforehand who the agent is

going to be selected by the President unless you yourselves put in the bill what agency it is to be, and if that agency is selected by Congress the regulations to be prescribed might be drawn up by that agency and approved by the President. Otherwise, it seems to me the President would have to delegate some of the authority under this act.

MR. WINGO: Isn't this the practical operation of it: If you didn't put that in there the President would be compelled in all of these agreements, etc., to sign the agreements when he would be unable for physical endurance to sign them. He would have to delegate it to somebody else. It would be simply impossible to read over all these regulations and inform on them, and he would have to rely on somebody else, and by putting this provision in you would permit him to do that by act of Congress and save him the physical labor of signing innumerable orders that he couldn't possibly pass upon?

MR. MANNING: The President would not be relieved from his authority by simply delegating somebody else—

MR. SANDERS: In the administration of fuel he delegated authority to the Fuel Administration, and he delegated it to the State fuel administration, and he delegated it to the county fuel administration, and the county fuel administration delegated that down to the township fuel administrator, and we have different arrangements in different places to carry out things which are entirely inconsistent. For instance, in the making of the regulations don't you think it would be wise to have the President act—I really think a violation of some of these regulations is to be a criminal offense—to the President of the United States. To be sure, he will not do it himself, but they will be his acts nevertheless, and when he signs his name to it and when the proclamation is issued the regulations will contain his name.

MR. MANNING: Under the explosives act we followed that method. The regulations were to be prescribed by the Bureau of Mines and approved by the President.

MR. WINGO: I have read this act as best I could. I think my friend has gotten a mistaken idea. I don't think there would anywhere be a criminal offense committed by a man for not following the provisions of it. We fix a penalty for violation of this act. Hoarding, under Section 4, any wilful violation of this section, shall be subject to fine. On page 7, any person who wilfully hoards shall be fined, and on the bottom of page 6 you will find the regulation for "any person who without a license issued carries on the business." It is not because he violates the regulations, but it is because he undertakes to do business without doing what Congress has prescribed he shall procure. And on page 8, "any person who destroys 'necessaries' shall be fined," and in the next section, "any person who conspires, combines, agrees, or arranges with any other person, or who aids or abets any other person (a) to limit the facilities for transporting, producing, manufacturing, supplying, storing, or dealing in any necessities; (b) to restrict the supply of any necessities; (c) to restrict the distribution of any necessities; (d) to prevent, limit, or lessen the manu-

facture or production of any necessities in order to enhance the price thereof, shall, upon conviction thereof, be fined not exceeding \$10,000 or be imprisoned for not more than two years, or both." So I think, my friend is mistaken about that as an abstract proposition. I looked for that, because I looked for criticism on that score. Nowhere would it become a criminal offense for a man to violate the regulations given him by the President, and my object in calling attention to it was that I didn't want the idea to get into the record we were permitting a man to get into the penitentiary—

MR. SANDERS: Under those provisions—take Section 15, page 16—there is a provision that when the President shall find that limitation, regulation, or prohibition of the use of any of these necessities is essential in order to assure an adequate and continuous supply of necessities, or that the national security and defense will be subserved thereby, he is authorized, from time to time, to prescribe and give public notice of the extent of the limitation, regulation, prohibition, or reduction so necessitated. Whenever such notice shall have been given and shall remain unrevoked all persons shall, after a reasonable time, prescribed in such notice, conform to the order providing such limitation, regulation, prohibition, or reduction. Any person who wilfully violates the provisions of this section, or who shall violate any rule or regulation made under this section, shall be punished by a fine not exceeding \$5000 or by imprisonment for not more than two years, or both.

MR. WINGO: Yes; and we have that in frequent acts. Whenever a President issues a proclamation, there is a formal notice. If he unwillingly violates it he is not guilty, but if he wilfully violates a proclamation made down by the President of the United States—

MR. SANDERS: That is what I say, the violation of the proclamation is made a criminal offense.

MR. WINGO: Yes; but he violates it, and he must have knowledge of it before he is guilty.

MR. SANDERS: I know; but you have to hunt up to whom the President delegates the authority.

MR. WINGO: You think that section would authorize somebody else to issue a proclamation?

MR. SANDERS: Yes; Section 2 says he may delegate anybody to do anything in this act.

MR. WINGO: I don't think the President could delegate somebody else to issue a proclamation of the President of the United States.

MR. SANDERS: It is in that section.

MR. WINGO: I don't think that would be taken into consideration.

MR. MANNING: Those of us who drew this bill will have to apologize for the phraseology. We followed the agricultural bill.

MR. DENISON: Do you think that by enactment of this legislation or the principles of this legislation that we can in this country produce, develop and produce, these necessities mentioned in the bill to sufficient extent to gradually if not ultimately supply our own needs?

MR. MANNING: With some few exceptions. Tin and

platinum—we are getting our platinum, as stated here yesterday and day before, very largely from Russia. A gentleman from the Ordnance Department called me up yesterday saying he wanted to negotiate for the purchase of platinum from Russia; he wanted to know how he could determine whether or not he was getting the pure article. I called his attention to the fact that we could get platinum from Colombia. There is a possibility of it in this country, also a possibility of getting it from the black sands of the Pacific coast. So far as tin is concerned, there is very little of it in this country. But I believe with American ingenuity we can find a substitute for it; we have done it for many commodities in the past.

MR. WINGO: Tin is of importance now?

MR. MANNING: It is an absolute necessity.

MR. HAMLIN: I want to ask you a question about it; I take it, if this bill becomes a law that duty will devolve very largely upon you?

MR. MANNING: I don't know that it will.

MR. HAMLIN: Well, somebody connected with the Bureau of Mines. It was suggested yesterday that there might be some objection to the licensing provision, commencing on line 14, page 15.

MR. MANNING: I think the license feature ought to be in. You are up against conditions now that should be controlled. For instance, suppose the Government should take over these two big sulphur mines in Texas and Louisiana. You would not only have to license the consumers but the producers. Some of this sulphur going into non-essential industries might have to be restricted.

MR. HAMLIN: I think Mr. Baruch has called special attention to this language in the bill, "that whenever and wherever the President in his judgment finds it necessary to fix the price and regulate the method of production, sale, shipment, distribution, apportionment, and storage that among dealers and consumers, domestic or foreign," would without a licensing feature give him ample authority. Personally, I like that license feature myself.

MR. MANNING: The only objection to the license system would be the enormous machinery you would have to handle, but it is only contemplated to license when it becomes necessary.

MR. HAMLIN: Have you had any trouble in administering the explosives law we passed last session?

MR. MANNING: None whatever. I have been much gratified with the ease with which that law is being operated.

MR. HAMLIN: Do you know of any reason why this couldn't be operated with the same ease?

MR. MANNING: I do not.

MR. GARLAND: Wasn't there considerable objection on the part of the small dealer to licensing?

MR. MANNING: Not that I heard of.

MR. GARLAND: Some of them told me they would not take out license; they would rather not sell.

MR. MANNING: I have heard of no real objection. All a man has to do is to be vouched for as to his loyalty and the license follows.

MR. SANDERS: Doesn't the license help you keep an inventory of what is going on?

MR. MANNING: No question about it. The Government was unable to get a complete record of the explosives plants in the United States until this law.

MR. SANDERS: Would you suggest that we make the license feature the same in the bill as we did finally in the explosives act, a 25-cent fee?

MR. MANNING: I don't know but what that ought to be in there.

MR. SANDERS: If you charge a fee it ought to be in the bill so as to show the authority, and no one would raise the question of the authority for doing it.

MR. MANNING: It might relieve the Government of the big expense of doing it. The consumer pays for the license.

MR. JAMES: A little while ago you said regarding that with American ingenuity and a little money something could very likely be done. Do you figure under this bill you could spend any money to help get any more manganese?

MR. MANNING: It isn't contemplated under that. The Bureau of Mines has \$150,000 recently given by Congress, and an estimate of \$100,000 more from the 1st of July, which will enable us to get valuable information concerning our mineral resources.

MR. JAMES: You didn't contemplate the appropriation of any money for this?

MR. MANNING: No, sir.

MR. LONDON: The suggestion was made yesterday of the establishment of a licensing system, that it would require the maintenance of a cumbersome machinery. You don't agree with that view?

MR. MANNING: Not if administered in the way we administered the explosives bill.

MR. LONDON: What are the technical ways for getting a license or applying for a license? A man applies for license in a written application?

MR. MANNING: Yes, sir. Under the provisions of the explosives law we have ten or twelve thousand licensing agencies in the United States, and it is easy for a man to go and get a license.

THE CHAIRMAN: As I understand, the county clerk is an agent?

MR. MANNING: Yes, sir; and every one of those clerks has been examined as to his loyalty.

THE CHAIRMAN: Are you having any trouble in getting any of these county and State officials on that duty?

MR. MANNING: Only by the State law. Some State laws require that the fees shall be turned over to the State treasurer.

THE CHAIRMAN: I know in one State they claim that there was some violation under the 'draft act,' and they prosecuted a man for it, and his contention was that the Congress had no authority to interpose that provision upon him, and the court held that he was right and he was discharged.

MR. SANDERS: That was the prosecuting attorney for my county. He was advised that he must advise the exemption boards. They hadn't called upon him, but they

trumped up a charge on him that he hadn't advised them about their duties. It wasn't any hesitancy on his account to do what the law asked him to do.

MR. MANNING: The purpose of the license is to restrict its use, the possibilities of restricting its use in certain non-essentials, and to create zoning districts.

THE CHAIRMAN: Would it destroy the efficiency, from your viewpoint, if we put in the law providing that all these people that are now dealing in these articles shall be licensed by the act, and as you find them unworthy of exercising the authority they should be revoked?

MR. MANNING: I think they should be revoked.

THE CHAIRMAN: The point I wanted to get at is, would it destroy the efficiency of what you are trying to get at by providing that all of the users and producers are hereby licensed?

MR. MANNING: I don't think that could be done. My understanding of the word 'license' means this—I will give you a concrete illustration of what the Food Administration did: All of the arsenic users were licensed because arsenic was needed for the War. The glass industry was told they couldn't use it, because they could get along without it, and told them what they could take in its place. What we may have to do is to apply the license and restrict its use. We want to encourage the production of it.

THE CHAIRMAN: Couldn't you license them under the law and wouldn't it save quite a—

MR. HAMLIN: His point is that the only remedy he would have if they didn't cease using it would be to revoke their license.

MR. MANNING: Under the operation of this bill we wouldn't start out to license any of the producers. We would say go ahead and produce all you can, but the time might come when we would want to take care of the material and apply a license, so as to get sufficient quantities for use.

MR. DENISON: I think it is very important to have the license, so as to limit the people who are to use it.

MR. SANDERS: The task of licensing people under this act would not be near so great as under the Food Administration act?

MR. MANNING: No, sir; because of the limited number of producers. We wouldn't want to discourage these producers by restraining them with a license. We want to protect them.

MR. JAMES: There are 14 or 15 minerals here. You don't have to use the license on more than one if you don't think it is necessary?

MR. MANNING: We may not have to apply it to any one.

MR. SANDERS: It is all up to the President, under section 5, to decide when that license is necessary?

MR. MANNING: Yes, sir.

ALUM is in large demand by manufacturers of paper, but transportation facilities are hard to get. The prices for lump ammonia alum are from 4 to 4½c. per pound; for lump potash alum, 8 to 9c.; for chrome-potash alum, 20 to 21c.; and for chrome-ammonia alum, 18 to 19 cents.

American Zinc Institute

At a meeting held at Joplin, on June 6, 1918, of mine-operators representing 88% of the total production of zinc ore produced in the Oklahoma, Kansas, and Missouri zinc districts, and controlling 35% of the present spelter production of the United States, there was formed an organization named the American Zinc Institute.

At this meeting complete zinc data relating to the zinc mining and smelting business of the United States were submitted. Correlating the data presented, the following facts relating to the mining and smelting industries were established:

1. The zinc industry met the requirements of the Government and of our Allies, as well as the requirements of the trade, during the first years of the War, and practically doubled production to meet this demand.

2. After the sudden requirements for war purposes were met, and the demand from this source decreased, there was likewise a marked decrease in consumption by the trade, because such industries as used galvanized products were diverted to the manufacturing of more essential war-materials.

3. It is estimated that during the life of the War the controlling consumption factor will show little betterment. Furthermore, the production factor in both spelter and ore can be controlled to exactly the requirements.

In the line with governmental policies clearly set out in many of the other industries and fairly administered by the War Industries Board, the following plans have been laid down:

(1) That each industry should strive to secure to the Government its necessary product, as well as that of the Allies and the trade, during the War.

(2) That consumption and production in any commodity should be equalized as nearly as possible, so that any industry embodying within itself non-essential factors shall release these factors for essential work. Thus each industry will release men, food-supplies, transportation, and capital for the more important and essential requirements of the Governments.

(3) That in order that our Government and the industries of this country may best lay plans for future export trade, it is necessary that those industries now suffering because of war and trade conditions shall be maintained as nearly as possible in a position enabling them to take advantage of foreign trade at the end of the War.

OIL PRODUCTION of the fields east of the Mississippi in 1917 was as under, according to the U. S. Geological Survey:

Field	Barrels	Increase or decrease, %
Appalachian (Pa., Ohio, W. Va., Ky., Tenn.)	24,907,176	+ 8
Lima-Indiana	3,669,963	— 6
North-west Ohio	2,901,861	— 7
Illinois	15,770,641	— 11
Indiana	759,102	— 1

The average price received at the wells for all grades of Appalachian oil marketed was \$3.11 per barrel, a gain of 65 cents over the price in 1916.

New Fume-Treatment Plant at Anaconda

By D. M. BROWN

A smoke-treatment plant, estimated to cost \$2,000,000, including the largest chimney in the world, is now under construction at the Washoe smelter, the reduction plant of the Anaconda Copper Mining Co., at Anaconda, Montana. The new plant is intended to recover a large quantity of the metalliferous dust now being discharged with the fume, all the arsenic, which now escapes, and a large portion of solids that are carried with

the inside of the pipe only, losing the value of the outer surface; the box-type treaters use the whole surface.

Treaters of the box type consist of a series of corrugated iron plates about 24 by 21 ft., placed in parallel and hung about 12 in. apart. Between the plates, chains are hung that are charged with approximately 75,000 volts, and supported by insulators on a gridiron framework. The chains are connected to the negative pole.

CONCRETE FOUNDATION OF NEW ANACONDA STACK

the smoke. This requires the building of a plant containing Cottrell treaters, a power-house, and the large chimney. The old stack is inadequate to carry the fume from the reverberatories, converters, and roasters.

In a northerly direction from the present stack will be two flues, each 20 by 50 ft. inside, one flue on the east and one on the west. These flues will lead to 20 Cottrell smoke-treaters of the Anaconda type. The Anaconda box-type Cottrell treaters were developed at the Washoe smelter. The Cottrell treaters of the old type consisted of a series of pipes of different sizes, averaging about 12 in. diameter; through the centre was strung a wire to carry the electric charge which caused the dust in the gases to drop. In this system the electric charge utilized

and the plates are grounded, resulting in a discharge from the chains to the plates. The dust-laden fume coming into the sphere of this electric action throws out the dust from the gases. The dust-particles become charged negatively and are attracted by the positive plates to which they cling until shaken by automatic shakers into hoppers provided for that purpose. Once the momentum of a moving dust-particle is retarded it is impossible for it to regain speed enough to ride with the fume. Electric power will be furnished by a 75-kva. single phase generator directly connected to a motor. A rectifier of the Anaconda type, 48 in. diameter, will be connected directly to the generator, changing the alternating into direct current to go to the chains.

A flue in four sections will be constructed opposite the treaters. Gas leaving the bottom flue on one side will pass through the treater where the solids are removed, and thence it will return to the upper flue which leads to the new stack. Dust caught in the main treaters is taken to a reverberatory furnace in small steel cars and charged with appropriate amounts of calcine, fluxes, and other materials.

The main flues will be built of steel and brick, the latter being in the form of hollow tile. Construction of the main flue will require 900 tons of steel and the hollow tile used will be equivalent to 2,500,000 common brick, weighing 7500 tons. The flues will pass 3,000,000 cu. ft. of gas per minute, carrying about 280 tons of solids per 24 hours, traveling at the rate of six feet per second.

It is expected that the treaters will catch 240 tons of solids per 24 hours or about 88% of the entire amount now going to waste. There will be 20 main treaters, five on each side in both flues, and each treater will be 20½ by 26 ft. inside. The building of the treaters will require 2600 tons of steel and tile, equivalent to 5,500,000 common brick, weighing 16,500 tons.

The reverberatory furnace for treating the dust will be 20 by 100 ft., and the steel building 68 by 154 ft. This building will be entirely of steel and will require 320 tons in its construction. The furnace will be fired with coal dust, consuming an average amount of about 60 tons per day. The charges used will consist of 240 tons of the main-treater dust, 45 tons of hot-treater dust, with 155 tons of calcine, flux, and other material. There should be an output of about 50 tons of matte and 200 tons of slag per day from this furnace.

This reverberatory furnace discharges fume, containing considerable dust and also volatilizes all the arsenic in the charge. The arsenic is recovered by leading it through a flue to a hot Cottrell treater where the remaining dust is deposited. The flue leading from the reverberatory furnace to the hot Cottrell treater is 33½ by 11½ ft. inside, requiring hollow tile equivalent to 376,000 common brick and weighing 1128 tons. The steel used in this flue will weigh 45 tons.

From here the gas enters a hot-treater. There will be three of these, 13 ft. 2½ in. by 23 ft. 6 in. inside, requiring tile equivalent to 75,000 common brick, and 400 tons of steel. The recovery in these treaters will be about 45 tons of dust per day with a gas-velocity of two feet per second. The escaping arsenic fume is carried through a flue and cold air is introduced at this point to bring the temperature down sufficiently to allow the arsenic to be deposited. The arsenic flue leading from the hot to the cold-treater will be 34 ft. 6 in. by 12 ft. 2½ in. inside, and will require hollow tile equivalent to 305,000 common brick, and 100 tons of steel. This flue leads to three cold-treaters, each 13 ft. 2½ in. by 23 ft. 6 in. inside. The gas velocity through the cold-treater will be about three or four feet per second. The arsenic fume led into the cold Cottrell treater is caught there. Any escaping gas or fume from the hot-treater is carried

through a flue to the main flue ahead of the main Cottrell treaters, making a closed circuit for the arsenic. There will be a recovery of about 35 tons of arsenic, 92 to 95% pure, each 24 hours. This will be shipped direct from the treater in that form, without further refining.

From the cold-treater to the main flue will be another flue 20 ft. by 12 ft. 2½ in. inside, equivalent to 206,000 common brick, weighing 618 tons, being the last link from the Cottrell apparatus to the big chimney. It is estimated that not over 15% of the dust will be carried away with the gases.

The electric current for the Cottrell treaters will be furnished from a power-house measuring 50 by 100 ft., and having a shop 21 by 43 ft., built of brick, steel, and concrete. The electric installation consists of 16 units; each unit a 75-kva. 220-volt single-phase generator, direct connected to a 115-hp. 2200-volt motor running at 1760 r.p.m. There will be a rectifier directly connected to the driving shaft of the generator to change the alternating to direct current, in which form it goes to the treaters. This power will be developed at 75,000 volts.

The new chimney, which is the largest in the world, will represent about 20% of the new investment in plant. The Alphonse-Custodis Co. of New York will construct the huge affair in approximately four months, using as much machine-power as possible, and a crew of 50 men. As the stack grows in height it is followed by an elevator tower built with compartments for seven cages. The speed of running will be 750 ft. per minute. The construction will require 2,300,000 radial brick, the equivalent of 7,000,000 common brick. The diameter of the chimney at the top will be 60 ft. and it will stand 525 ft. above its concrete foundation. The Tacoma stack has a diameter of 23 ft. and stands 571 ft. high. The draught-height of the Washoe stack, due to its position on a hill top, will be increased 454 ft. from the reverberatory to the top of the new stack, equal to a draught-column 979 ft. high. The chimney will have two flue openings, each being 61 ft. wide and 60 ft. high. For a distance of 68 ft. above the foundation the chimney will be octagonal and from that point it will be round. This stack will transmit 3,000,000 cu. ft. of gas, plus 1,000,000 cu. ft. of cooling-air, or a total of 4,000,000 cu. ft. per minute, at a velocity of 24 ft. per second.

The new stack will be used entirely to conduct fume from the smelter to the higher atmosphere. All other chimneys now in use will be eliminated and their flues connected to this main one, and all the fume will pass through the main flue and the Cottrell treaters. The increased draught will avoid the escape of gases, which now is common about the works.

A record was made in the pouring of the foundation for this great stack last fall. It took but 24 shifts to pour 5000 cu. yd. of concrete, and one of the shifts was spent in machine repair so that the actual time was but 23 shifts. The pouring of an equal volume at the Tacoma stack required 45 shifts and the foundation of the Japanese chimney, consisting of 2711 cu. yd., required 90 shifts to pour.

Comparison of the World's Largest Stacks

	Brick				Reinforced concrete Saganoscki, Japan.
	New stack, Anaconda,	Old stack, Anaconda,	Great Falls,	Tacoma,	
	ft.	ft. in.	ft. in.	ft. in.	ft. in.
Inside diam. at top	60	30 0	50 0	23 11	26 3
Inside diam. at bottom	76	31 4	...	39 0	37 9
Thickness of wall at top	18	12 6	18 0	13 6	0 7
Thickness of wall at bottom	5	5 2	5 6	5 1	2 5½
Height above foundation	525	300 0	506 0	571 0	570 0

For the construction work and as a permanent track-age for hauling material, three miles of main-line spur and switch-back had to be built, and also a wagon road

OLD ANACONDA FLUE AND STACK

a mile long. In excavating and grading for the wagon road and for the site of the plant nearly 85,000 cu. yd. of earth and rock were moved.

Three important results will be obtained by the installation of the new Cottrell plant, namely, the saving of metalliferous dust, the elimination of gases about the plant, and the improvement of agriculture in the Deer Lodge valley. The arsenic that fell upon the farm lands of the valley has given rise to complaint and litigation in the past, but with the elimination of this factor real-estate values in the adjacent country will advance.

The men responsible for the construction of the plant

are Fredrick Laist, the general manager of the smelters for the Anaconda company, W. C. Capron, the mechanical superintendent for the company, under whose immediate direction the construction is made, and J. K. Murphy who will superintend the new plant, he having had charge of the experimental Cottrell treaters now in use at the works. It will stand out as the most notable equipment in America for the abatement of fume difficulties, considered both as to the effect on agriculture and as to the loss entailed on the smelter by the valuable products ordinarily swept into the atmosphere.

A NEW separation of tin and tungsten in stanniferous wolfram is given in the 'Compt. Rend.' (165, 408-10) as follows: Pulverize the mineral carefully and fuse it with anhydrous Na_2SO_3 . Take up the fused mass with boiling H_2O , dilute the solution to 700 or 800 cc., and acidify it slightly. The brown SnS precipitate obtained entrains with it some SiO_2 and sulphides of Mn and Fe, but no H_2WO_4 . To purify the precipitate dissolve it in $(\text{NH}_4)_2\text{S}_2$, re-precipitate it as SnS_2 , and calcine it to SnO_2 . To determine the tungsten fuse another sample with Na_2SO_3 and take up the mass directly with aqua regia, causing thereby the precipitation of the major part of the H_2WO_4 along with SiO_2 . The separation is not quantitative, however, because of the presence of metatungstic acid. Treat the filtrate, which should contain Fe (the 10% usually present in the mineral is sufficient) with NH_4OH , without excess, to bring down the $\text{Fe}(\text{OH})_3$, which entrains the tungstic acid. Wash the precipitate free from sodium salts, dissolve it on the filter with 50% HCl solution, evaporate the filtrate to dryness, and take up the residue with HCl . Separate the SiO_2 by the ordinary methods. The H_2WO_4 retains only traces of iron, less than 0.2 mg. Fe_2O_3 .

EFFECT of rate of application of load on the compressive strength of concrete is discussed by D. A. Abrams, in the Proceedings of the American Society for Testing Materials. He points out that in compression tests of concrete, the rate of application of load has an important influence on its strength. Tests were made at the structural-materials laboratory of Lewis Institute, Chicago, on 270 concrete cylinders, 6 in. diam., 12 in. high, with mixes of 1:9, 1:5, and 1:3. Two methods of loading were used: 1. About 10% maximum load was applied at a fast rate (0.25 in. per min.) and the remainder of the load applied at rates from 0.006 to 0.15 in. per minute. 2. About 88% of maximum load was applied at a fast rate (0.25 in. per min.) and the remainder at a rate of 0.01 in. per minute. For the richest mixes, tested at 28 days, the strength, when loaded at 0.15 in. per minute, is 14 to 20% higher than when loaded at 0.006 in. per minute. If part of the load is applied at a fast rate and the rest at a slow speed the ultimate strength of the concrete is unchanged. A machine-speed which gives a shortening of the test piece of 0.01 to 0.02 in. per minute per foot is recommended as a standard rate for compression tests of concrete.

Engineering Council Seeks Helpers

The Engineering Council, as was designed, is engaging in numerous activities for the engineering profession of America, many of these activities being directly or indirectly connected with the War. The Council is a body of representatives from member-societies conducting most of its work through committees. For effectiveness these committees have usually a small number of members, although committee-membership is not limited to the representatives on the Engineering Council. Men have been selected for committee-membership because of broad knowledge and extended experience in the field. As the work of some committees develops, however, there are occasions when helpers are needed who can devote time to details, to special investigations, to getting local information in some community or State, to compiling and analyzing information already accumulated, or to scouting for men needed for some particular service. When need arises for such assistance it is often difficult to think of or to find the right man available at that moment. In order to meet this difficulty, to give a larger number of engineers a share in the activities, to broaden the Council's contact and gain greater breadth for its views and statements, as well as to make its work more widely known, the Engineering Council is requesting engineers who can help, to register their names and addresses, and in a general way stating the extent and nature of the service each is willing to render. This is an opportunity for some of the younger members of the profession to take a hand in society activities, but the request is not limited to the men of few years. Of course, every one registered may not be called upon or it may be a long time seemingly before a given volunteer is asked to help. On the other hand, calls may come promptly and frequently and opportunities may be afforded for service of no small value to the profession and the public.

To indicate a few lines of the Council's work, brief statements are given about some of the committees. The Public Affairs Committee reports on matters of public policy, and those relating to National, State, or local government, other than technical questions. One question of active interest now before this committee, for example, is that of licensing engineers.

The American Engineering Service has the duty of compiling as complete a classified catalogue of the engineers of America as it may be practicable to get together. Much information has been assembled, but a great deal remains to be collected. During war time lists collected by this committee and the engineering societies co-operating with it, are being used to supply thousands of names in response to calls from Government departments for specialists for combatant and other forces of Army and Navy and for the war industries. This committee frequently could use volunteers not only in New York but in distant communities, also in scouting for men to meet special and urgent calls from the Government, as well as in other ways. The War Committee of Technical Societies is engaged upon the examination of new inven-

tions offered to the War and Navy departments and to stimulation of the development of useful new appliances for warfare. In reviewing ideas received, preparing bulletins and writing reports and records, this committee could make use of a number of helpers from time to time. The Water Conservation Committee is organizing to deal with questions of policy in various parts of the country concerning the utilization and control of water for such purposes as power development, navigation, irrigation, and municipal supply. This committee will need correspondents to aid it in keeping informed or in making special investigations about local laws and policies.

Engineers who are able and willing to take some part in this service for the profession should communicate with Alfred D. Flinn, Secretary of the Engineering Council, 29 West 39th St., New York.

CORRELATION between bacterial activity and lime requirement of soils was the subject of experiments made by F. E. Bear on two acid soils, which had received no lime or fertilizers for a number of years. Tests were conducted to determine the effect of CaCO_3 , in amounts ranging from 250 to 40,000 lb. in 2,000,000 lb. of soil, in the following: The number of bacteria, the rate of ammonification, the rate of nitrification, the fixation of nitrogen by non-symbiotic organisms, and the development of bacteria radicola of the soy bean. The greatest relative increase in the rate of ammonification of casein per unit of CaCO_3 applied, occurred with the application of 2000 lb. of CaCO_3 per 2,000,000 lb. of soil. There was no marked increase as the neutral point was passed. Amounts as high as 20,000 and 40,000 lb. caused a slight decrease in ammonification. The addition of CaCO_3 is followed by an increased nitrification, which correlates almost directly with the increased applications of CaCO_3 , up to 5000 lb. per 2,000,000 lb. of soil. There is not a corresponding increase above 5000 lb. There is no close correlation between the increased number of bacteria in the soil and the rate of nitrification except that in general the applications of increased amounts of CaCO_3 caused an upward tendency in the number of bacteria as well as in the rate of nitrification. The number of root nodules of soy beans had a tendency to increase in these acid soils with small applications of CaCO_3 . The application of $\text{CaH}_4(\text{PO}_4)_2$ was necessary for maximum N fixation. This was decreased with large applications of CaCO_3 . The pulverizing of limestone is becoming a great industry in this country, as the value of such material becomes better appreciated. Pulverized limestone, gypsum, and sulphur all promote nitrogen-fixation in soils to a remarkable degree. The greatest advantage is obtained when all three are used together on soils rich in humus.

CYANIDE OF SODA is not in heavy demand at the present time, and producers are asking 37c. per pound, while re-sale material is quoted at 40c. in carload lots, and at 42c. in smaller quantities.

REVIEW OF MINING

SAN FRANCISCO, CALIFORNIA

The Antimony Situation Discussed at a Public Conference.

The United States Tariff Commission held a public conference on the antimony industry at San Francisco on June 24. W. S. Culbertson was chairman, with Guy C. Riddell as metallurgical expert. There were 20 present, exclusive of officials. Producers were called first:

H. J. Hibschan, representing the Coeur d'Alene Antimony and Star Antimony companies on Pine creek, near Kellogg, Idaho, said that the deposits were worked 20 years ago. A mill and flotation plant is ready to work at the former. The other property is not much developed, and is closed at present. There is another antimony mine near Wallace. Gold is associated with antimony in Pine Creek ores. Chinese competition he considers too severe for domestic operation.

M. E. Jolley of the Coeur d'Alene Antimony Co., Idaho, stated that labor and supplies are very high. In 1915 the market was high, then it dropped suddenly, resulting in the present situation. He had investigated the caustic-soda and electrolytic methods of extracting the metal.

Chalmer Munday represented F. S. Houghland of Montana. In the Burns district, 15 miles out of Thompson Falls, considerable deposits have been worked irregularly for 20 years. Some shipments in 1915 resulted in loss. A local oxide plant was erected for low-grade ore. No work is being done now on account of the uncertainty of the market. He considered 25c. per pound a desirable price.

C. N. Miller represented Miller & Thompson, operating on the West Coast of Sonora, Mexico. Their ore is an oxide, but deposits are irregular. They have been shipping 400 tons per month, hauling 110 miles to Santa Ana by wagon. They prefer to mine in the United States but economic conditions in Mexico are better, especially with cheaper labor. The wage is \$2 per day, equal to \$1 in the United States. The pay in China is 10 to 40 cents. The Mexican ores carry no impurities. The present price is too low, although they are just making ends meet. He suggested a higher tariff on metal in ore. It costs \$60 per ton to place ore at Harbor City, Los Angeles, by wagon and rail.

The smelter interests were called next:

M. Elsassar of the Western Metals Co., Los Angeles, an authority on the subject, read a prepared statement. Labor is the deciding factor in antimony production everywhere, and we have to combat cheap help as in China, Bolivia, and Mexico. It is pre-eminently a war metal. It is generally stated that there are no American deposits of importance. They are admittedly erratic. The market in past years has hindered development. Practically no machinery has been erected at antimony mines on account of the market. The present tariff is no protection. A duty of 2c. per lb. on metal in ore is desired, and 6c. on metal and products. Great Britain has fixed antimony at 18.6c. per lb. A Chinese product (71.8% Sb) can be landed in New York at 11c. The trade requires the 'star' metal, which is unnecessary. Antimonial-lead ore is ignored. Machinery is not a factor in mining and smelting. Stibnite can easily be floated. Kern county, California, has large possibilities. The antimony consumption of the United States is now 1500 tons

per month, about double the normal. A reasonable price is 16 cents, and the miner could be paid a fair price, that is, the Chinese cost of 10c. plus 6c. duty. There is no monopoly of the metal in America. \$85 per ton for 50% ore should be profitable mining; this is equal to \$1.75 per unit. France has a considerable antimony industry protected by a tariff. The Western Metals Co.'s costs are 5½ to 6c. per pound for smelting and freight to New York. Antimony producers have asked the War Industries Board to fix the price, otherwise they want a duty. The Chinese cost plus a duty would fix the price.

W. C. Chalmers, connected with the Wah Chang Mining & Smelting Co., did not think it was worth while fostering so small an industry. The Chinese export duty on antimony is 5% on the value of the product at point of shipment.

G. McN. Ross gave the attitude of mine-owners and lessees especially of Kern county, California; Humboldt county, Nevada; and Alaska. The men wish to do all in their power to help the industry. He thinks that there is a great deal of antimony ore in America. The Nevada sulphide ore is easily sorted and concentrated, but the oxide is not. He gave some interesting views on the tariff; and thought that with a high price the output of antimony should improve just as it stimulated chrome mining.

Fletcher McN. Hamilton, State Mineralogist, said that until 1915 there was practically no interest taken in antimony production. Up to 1915 there was 510 tons produced. From July 1914 the price increased from 5½ to 44c. in January 1916, due to speculation. Californian deposits are in Kern, Inyo, and San Bernardino counties. In 1916 the output was 1015 tons of ore, and in 1917, 150 tons, concurrent with the drop in price. Production follows high prices, and there is little at present. There is no stability in the market; this curtails prospecting and development. A protective tariff is advisable.

Fred West, chemist of the U. S. Customs, said that a shipment of needle antimony in May 1917 came to San Francisco, the first for several years, from the Wah Chang company, in China. There was no classification for this, carrying 71.4% antimony. It was eventually termed matte. A duty of 10% was charged on it. His views led to an interesting discussion on what was antimony metal and what were the ores, etc. Guy C. Riddell considered the terms in the antimony trade as very confusing. W. W. Bradley, of the State Mining Bureau, gave definitions of concentrate and crude, as used metallurgically, distinguishing them from the antimony trade terms.

F. L. Ransome, of the U. S. Geological Survey, said that no estimates had been given by witnesses on the reserves of antimony ore in this country.

C. Solomon Jr., of the Chapman Smelting Co., San Francisco, was very deliberate. He said that the Chinese sold ore in London prior to the War at £5 or £6 (\$24 to \$29) per ton. A duty of \$10 per ton would not prevent them from shipping it to the United States and smelting it here, so eliminating American miners. A natural sequence to a tariff would be that the Chinese would erect smelters here. He suggested a bounty of 3c. per pound to American producers, also 5c. to United States smelters, and removing all tariff duties.

DENVER, COLORADO

United States Tariff Commission Investigates Colorado Tungsten Industry.

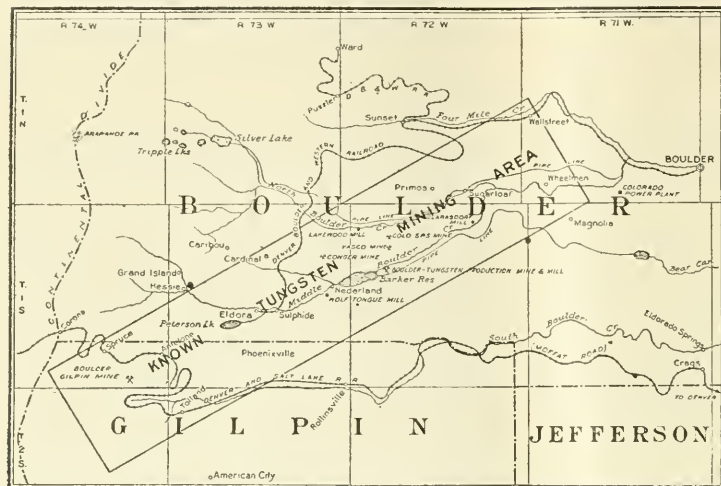

The conference opened at Denver on June 17 and continued through four sessions, adjourning the next day. The Commission was represented by E. P. Costigan, chairman, and Guy C. Riddell, metallurgical expert for the U. S. Bureau of Mines. To prepare the way for effective progress at the sessions, the Commission had previously distributed questionnaires among the tungsten producers and millmen of the State. Of the several hundred sent out, there were received 75 replies. Failure to secure more was due to the fact that activities in the tungsten field during recent years have, in the majority, been conducted by prospectors and miners who, working in a small way, kept no records.

sten in this country. Feeling thus at ease, important statements were made and discussions were entered into by men representing every phase of the industry, not omitting the unionist side, represented by a miner from Boulder county. Among those taking part in the proceedings were: Warren F. Bleecker, manager of the Tungsten Products Co.; Nelson Franklin, manager of the Rare Metal Ores Co. and the Black Metal Mining Co.; I. N. Bair, lessee at the Good Friday mine, Boulder county; Edwin E. Chase, mining engineer of Denver; Frank Armstrong, Boulder engineer; Emerson J. Short, Denver attorney with tungsten mining interests; Robert M. Keeney, manager and metallurgist of the Ferro Alloys Co.; M. B. Tomblin, secretary of the Colorado Chapter American Mining Congress; W. B. Stoddard, manager of the Black Metal Reduction Co.; Frank E. Safely, lessee in mines; J. B. Finlay, president of the Colonial Steel Co.;

George Rogers, owner of extensive valuable tungsten mining property in the Nederland district; John McKenna, president of the Vasco Mining Co.; and Harold Boericke, secretary-manager of the Primos Mining & Milling Company.

The Commission was presented with a printed statement on the condition of the tungsten mining industry in Boulder prepared by a committee of 12 representative men, including managers of large companies, lessees, small miners, and operators of concentration mills and reduction works. This statement is so comprehensive in its scope that very few points were left for the Commission's committee to bring out at the hearing. The sessions were therefore largely devoted to an enlargement of the vital points in this statement.

Boulder county is the only section of Colorado that has made any appreciable production of tungsten ores. Consequently al-

THE TUNGSTEN AREA OF COLORADO

The Commission had made it clear that, when desired by any operator, the reply would be held in confidence. Notwithstanding this privilege, the replies were all given in a generous disposition with no request for privacy. The data contained in these questionnaires will be the basis for the tabulation of valuable statistics.

Among the points the Commission desired to bring out specifically during the public session at Denver were the following:

What is the present condition of the tungsten industry in Colorado and what developments have transpired since the Tariff Act of October 3, 1913? To what extent can American deposits and production supply our domestic requirements? Due to war disturbances, what effects have been noted in the production of tungsten, in labor conditions, markets, and plant extensions? What are the costs of production in 1918 compared with those in 1913 and 1914? What can be set as a minimum price for tungsten ore at which American mining and reduction operations may be expected to show a reasonable profit? Are there any new treatment processes either in this country or abroad that may affect competitive American production?

Mr. Costigan's opening remarks made it clear to all present that the hearing was strictly informal in nature and that witnesses might express themselves in their own way and words, without oath, to the end of giving the Commission as much information as possible to assist it in arriving at a solution of the problem of stimulating mining of tung-

sten in this country. Feeling thus at ease, important statements were made and discussions were entered into by men representing every phase of the industry, not omitting the unionist side, represented by a miner from Boulder county. Among those taking part in the proceedings were: Warren F. Bleecker, manager of the Tungsten Products Co.; Nelson Franklin, manager of the Rare Metal Ores Co. and the Black Metal Mining Co.; I. N. Bair, lessee at the Good Friday mine, Boulder county; Edwin E. Chase, mining engineer of Denver; Frank Armstrong, Boulder engineer; Emerson J. Short, Denver attorney with tungsten mining interests; Robert M. Keeney, manager and metallurgist of the Ferro Alloys Co.; M. B. Tomblin, secretary of the Colorado Chapter American Mining Congress; W. B. Stoddard, manager of the Black Metal Reduction Co.; Frank E. Safely, lessee in mines; J. B. Finlay, president of the Colonial Steel Co.; George Rogers, owner of extensive valuable tungsten mining property in the Nederland district; John McKenna, president of the Vasco Mining Co.; and Harold Boericke, secretary-manager of the Primos Mining & Milling Company.

The Commission was presented with a printed statement on the condition of the tungsten mining industry in Boulder prepared by a committee of 12 representative men, including managers of large companies, lessees, small miners, and operators of concentration mills and reduction works. This statement is so comprehensive in its scope that very few points were left for the Commission's committee to bring out at the hearing. The sessions were therefore largely devoted to an enlargement of the vital points in this statement. Boulder county is the only section of Colorado that has made any appreciable production of tungsten ores. Consequently almost all the witnesses represented interests in that county. Other data were given concerning small production in Gilpin, Park, Pitkin, Ouray, San Juan, Fremont, and Gunnison counties, but the prevailing opinion was that no development would be attempted in these districts unless the price for tungsten ore and concentrate shall materially advance. The belief was general, also, that prospecting in the Boulder county belt—now at a total standstill—will not be resumed until not only a favorable price for the commercial products shall be established, but until, through Federal means, such a price shall be stabilized.

The testimony presented proved that two companies, organized primarily to manufacture ferro-tungsten in Colorado, have discontinued such work entirely. These are the Boulder Tungsten Production Co. and the Ferro Alloys Co. The latter is now making ferro-chrome exclusively. The only firms that are meeting with success in the mining and milling of tungsten ores, with a single exception, are three companies that are subsidiary to strong steel companies in the East. These are the Vasco Mining Co., selling its concentrate to the Vanadium Alloys Steel Co.; the Primos Mining & Milling Co., whose product goes directly to the Primos Chemical Co.; and the Wolf Tongue Mining Co., having direct connection with the Pirth-Stirling Steel Co. The exception mentioned is the Tungsten Products Co., which mines part of its ore, purchases custom ore, and manufactures ferro-tungsten and tungstic acid that is sold to various Eastern consumers.

In Boulder county most of the mining is done under the leasing system. There are no fixed rules regarding the terms upon which leasing is done. As shown by the testimony of Mr. Conklin, manager of the Vasco Mining Co., it is the practice of his company to render substantial assistance to its lessees whenever they are obliged to incur extra expense in the development or equipment of their blocks of ground. In all such instances, the company advances one-half of the cash necessary to continue the dead work. If success is attained, the company is reimbursed from the lessee's production; if failure follows, the company loses equally with the lessee. There is no uniformity in regard to royalties, every lease being gauged upon conditions. Royalties vary between 5 and 50% on mill returns.

Considerable discussion centred about the variable prices paid for ores of different grades. It has been common complaint among small miners that they are robbed by the purchasers of their ore; but the evidence presented at this hearing tended to prove that the millman does not make an exorbitant profit at any time, and frequently meets with losses. Figures of cost of concentrating low-grade tungsten were given by several mill operators. These figures differed considerably, the discrepancies being due, probably, to the different schemes used in the respective plants and to differences in capacity. The statement made by one was that it cost his company approximately \$20 to concentrate one ton of 10% ore into 60% product.

According to testimony of well-informed witnesses, the quotations on tungsten concentrate as published in periodicals are always false, in every instance being considerably higher than such product commands in the market. Whereas, on June 15, the technical press gives a quotation of \$19 to \$24 per unit, it appears that transactions could not be made at such figures, but probably around \$16 to \$18.

The stabilizing in the market for ore and products was the keynote of all the remedies suggested for improving conditions in the American tungsten industry. It was thought that the Government should be able to establish an invariable price of from \$30 to \$40 per unit WO₃, based upon 60% product.

CRIPPLE CREEK, COLORADO

Half-Year's Dividends.—First-Aid Work.—Leasing Notes.—Drainage-Tunnel.

Dividends paid by Cripple Creek companies in the first half of the current year total \$1,215,000, as follows: Cresson, \$732,000 (6 monthly disbursements of \$122,000 each); Golden Cycle, 6 monthly, \$270,000; Portland, 2 quarterly, \$180,000; and Granite, 2 bi-monthly, \$33,000.

The U. S. Bureau of Mines safety-car No. 2 arrived here on June 16, to remain a month. Classes will be formed for first-aid and mine-rescue work.

A general leasing policy has been adopted by the Portland company, and all levels above No. 15 have been leased or are open for lease. By this method miners are obtainable, who would not otherwise work for wages.

The Komat Leasing Co., operating the Victor mine on Bull Cliffs, is unwatering the bottom or 14th level, at a depth of 1000 ft. No work has been done on this level for years.

Lessees at the Eltkon produced 500 tons of 1-oz. ore in May.

The Acacia, with two sets of lessees, shipped 200 tons of \$8 to \$40 per ton.

The Roosevelt drainage-tunnel, due to labor shortage, was advanced only 49 ft. last month. The Portland drift at the tunnel-level was driven 252 ft. and the Cresson drift on the Funeral dike 212 ft. The flow from the tunnel has fallen to 3100 gal. per minute.

United Gold Mines production for May total 3000 tons,

valued at \$60,000 gross. The active properties of this company are the Trail mine and tunnel on Bull hill, W. P. H. on Ironclad hill, Bonanza on Battle mountain, and Wild Horse on Bull hill. All are operated under lease.

REPUBLIC, WASHINGTON

Recent Activities at Republic and in Okanogan County.

In the old Republic mine there is 45,000 to 50,000 tons of ore assaying from \$4 to \$6 per ton awaiting a cheap method of treatment. On the 200-ft. level two carloads of marketable ore is being broken monthly for shipment to smelters. The richer ore in the foot-wall is nearly exhausted.

In the Last Chance mine the Lone Pine-Surprise company is prospecting the hanging wall by diamond drilling east beyond the main orebody on the 500-ft. level. This is being done because of stringers of quartz running off diagonally from the main body, rendering the hanging-wall area uncertain. Shipments total 1200 tons per month.

At the Knob Hill modern improvements indicate a belief in a future of the mine. The portal of the main adit has been concreted, and since the new shaft was sunk, a head-frame, 50 ft. high, has been erected and equipped with an automatic device for tipping the bucket and delivering a ton of ore into a bin. From this the ore is delivered into a car of equal capacity and taken to a platform to be sorted and transferred to an ore-bin, whence it is delivered to railway cars for shipment. All material is automatically handled. The tracks are covered with sheds. New buildings have been erected for a blacksmith-shop, change-room, store-room, powder-house, and sheds for the machinery. Mr. Daily is local manager, and Alexander McKay is superintendent. The drift from the new 200-ft. level is now under the old stopes, and the quality of the ore is improving.

In the Surprise mine six men are employed on two shifts driving north on the 300-ft. level, from a point north of the main incline shaft, into virgin ground. From the workings on the Clark adit 250 tons of ore is the weekly output.

Since the Consolidated Mining & Smelting Co. of Canada purchased the San Poil mine, considerable work has been done with diamond-drills for the purpose of proving the continuity of the vein on its pitch. The surface workings are under lease to John McKay, who is shipping ore.

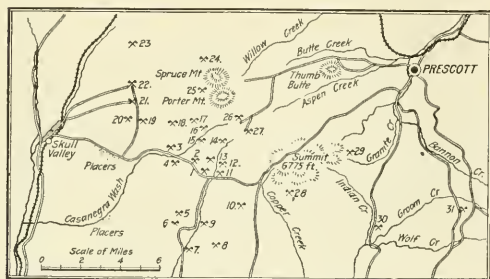

The American Flag mine at Sheridan, Okanogan county, near the Ferry County boundary line, is producing considerable ore, which assays from \$10 to \$200 per ton. About 200 tons has been mined and raised from development. The gangue is quartz, 7 to 15 ft. wide. A shaft has been sunk on it 100 ft., and a drift follows the hanging wall. Ore assaying up to \$20 per ton carries from 80c. to \$1.25 per ton gold, the remainder in silver. The nearest haul to the Spokane and British Columbia railway is eight miles, costing \$3 per ton. The mine is owned by Maurice Snyder and Mr. Hoover.

The Nutria and Aztec mines, near Chesaw, in Okanogan county, on Copper mountain, owned by J. M. Lynch, has been bonded through Horace Smalley to Volney Williamson and associates of Spokane for \$15,000, the bond to run 18 months from April 18. The first payment is due July 15. The product is magnetite, containing 2% copper. About 400 tons on the dump will be hauled by motor-truck to Mincester, B. C., for shipment over the Great Northern railway to a smelter, where it will be mixed with Chewelah (Stevens county) magnetite. The mine is opened by quarrying, breaking 100 tons per day. The Aztec adjoins the Nutria on the west. The ore contains a little more copper than the Nutria, and 4 oz. of silver per ton, and they both run in continuous deposits east and west up and across the mountain. The Aztec ore differs from the Nutria in that it is pyrrhotite.

ARIZONA

Copper Basin.—The centre of this district is 12 miles south-west of Prescott. Mining was started in 1879. A smelter was burned in 1893. Up to 1902 the field was dormant, when a revival set in. Since then there has been a good deal of work done. The accompanying map, re-drawn from 'Yavapai,' shows the principal mines. The Commercial is shipping 140 tons of ore daily. The Lucky 5 has 2600

MINES IN THE COPPER BASIN DISTRICT, ARIZONA, AS UNDER:

- | | | |
|---------------------|------------------------|----------------------|
| 1. Commercial | 11. Loma Prieta | 22. Logan |
| 2. Phelps-Dodge) | 12. Martin Schuber | 23. Martin |
| 3. Copper Hill | 13. Herman Boehm | 24. Derby |
| 4. U. S. Navy | 14. Arizona Opal | 25. Queen |
| 5. Big Butte | 15. Plymouth | 26. Zachariah |
| 6. Tri-Metallic | 16. Alto | 27. Thumb Butte Con. |
| 7. Lucky 5 | 17. Oregon | 28. Beard |
| 8. War Eagle | 18. Robinson (Russell) | 29. Comet |
| 9. Arizona Portland | 19. Gold Star | 30. Silver King |
| 10. Sink to Rise | 20. Jerome Prescott | 31. Ruth |
| | 21. Copper Valley | |

tons on the dump. In the Loma Prieta is over 500,000 tons of 1.3% ore. Some of the mines are worked in a small way, others are awaiting buyers.

Oatman.—Gold production of United Eastern in May was \$290 tons averaging \$22.44 per ton. During 17 months' operations, 125,000 tons of ore has assayed \$22 per ton, of which 96% was extracted. Twelve dividends of 5c. each total \$818,000.

Swansea.—The 500-ft. three-compartment shaft of the Swansea mines has been completed, and driving on the ore-body is in progress. A 200-ton mill is being erected.

Yuma.—The Red Cloud Consolidated Mines Co. is remodeling its mill. The mine should be a fair producer. About 30 men are employed.

CALIFORNIA

Happy Camp.—The manager, William Koerner, of the Gray Eagle copper mine, owned by the Mason Valley company of Nevada, reports that the company has completed development of the mine and is laying off its men, who have averaged 70 during the past two years. Lack of transportation is the cause, and the next move is the construction of a railway or other facilities into the district. Chrome development is active in this district. Seven rich discoveries have been recorded during the past week.

Ingot.—The Afterthought Copper Co., as already mentioned in these columns, has closed its plant here, and will

as soon as possible construct an electrolytic zinc plant, and a reverberatory-furnace for the copper concentrate. It was found that payment for freight, trucking to rail, treatment charges on concentrate, and metallurgical losses were more than \$150,000 per month. This can be saved by local treatment.

Oroville.—The Western Ore Co. has shipped its first car-load of chrome concentrate. The mill is producing 12 tons of this product daily. The deposits are at Limestone, on the Oroville-Paradise road.

Tuolumne.—This old mining town in Tuolumne county was mostly destroyed by fire on June 17.

COLORADO

Creede.—Silver-gold ore shipments from this district are nearly 150 tons daily. The Creede Exploration Co. supplies about half of this. The Equity Creede company has uncovered 33 oz. silver and \$3 gold ore on a lower level.

Denver.—The U. S. Tariff Commission met here on the 17th to discuss the tungsten situation. It was argued by producers that the ore is being mined at a loss, even at \$22 per unit. An increase in price was suggested and a tariff on imports.

Dumont.—B. C. West has lately taken over the old La Maynan group of eight claims. He will hurry development and take out shipping ore. The main tunnel is in 1200 ft. on a vein 6 to 25 ft. wide, high in lead and silver. The most noted property at Dumont is the Albro, under lease and bond for two years to Mrs. Dingle and son. They are shipping high-grade copper and silver ore regularly to the Globe smelter at Denver.—The amalgamation and concentration mill of C. Lirschen at Dumont is in commission only about half time, then only with 15 of the 30 stamps. The main reason is that wages are so high at the copper centres of Montana and Arizona that few first-class miners are left in Colorado. This mill is complete, and the owner states that he could easily mine and treat 100 tons per day if he could get men. The ore carries silver, gold, and copper.

Lawson.—The mill of the Little Giant M. & N. Co. and T. & T. Co. is now in operation. It is equipped with Blake crusher, ball and tube-mills, and three concentrating tables, and a 6-cell flotation plant. The mine has been extensively developed. Mrs. Etta Myneer is manager and R. B. Martin is superintendent.

Ophir.—The New Dominion has installed an air-compressor, drills, and milling machinery.

Freighting outfits are getting ready to move the season's output of carnotite ore, from Paradox Valley and nearby fields. The Standard Chemical Co. at Naturita is shipping 20 truck-loads of carnotite daily. A large number of men are employed.

The Mount Blaine Oil Shale Co. is having a still constructed at Denver. In order to test it before it is shipped to the mine. Three tons of shale has been sent to Denver.

The Butterfly mine will start milling as soon as a good head of water is available. A large amount of ore is ready.

The Ophir Loop Mines Co. has leased the Silver Bell mine and a shipment has been made by the new lessees.

The San Bernardo mine at Matterhorn bids fair to be-

come one of the main producers of the district, as it has shipped two cars of ore.

Manganese claim-owners here are interested in processes for dressing low-grade ore.

The Carbonero is shipping crude ore in large quantities.

Ouray.—The Ouray Smelting & Refining Co. has made several changes in its mill below the town. The Messberg flotation unit has been removed, and a Hyde machine put in its place. An addition is a Deister slime-table. The laboratory is now available for testing the various ores of the district. It is well fitted with a baby Wilfley flotation machine, three sets of flotation experiment machines, and full sets of sizers. T. B. Crawford is manager for the company. Ore from the Gem, Calliope, Float, and Wedge mines will be milled, and a special effort made to reduce the silica content, so as to put out a high-grade shipping product.

Red Mountain.—The Red Mountain district is still covered with a heavy blanket of snow, and rail transportation remains at a standstill.

The Summit Copper Mining & Milling Co. has a large number of men working on the old San Antonia claims. At present they are putting up a raise to open a large body of ore. Large shipments will start as soon as the Red Mountain line is open.

Telluride.—The Alta mine suffered a loss of \$10,000 when a fire, starting in the stables, extended to the blacksmith shop, compressor-house, tramway terminal, and snowsheds. All buildings and contents were lost. The compressor was ruined, and four mules in the stable were burned. It is believed that the fire was caused by a similar accident as that at the Tomboy, when its new bunk-house was burned. In this case a lighted carbide lamp had been left blazing against the wall of the bunk-house, and at the Alta the opinion is that either a lantern or a candle was left burning in the stables. When the terminal burned down, the entire tramway, $\frac{3}{4}$ mile long, collapsed, but the towers were not broken, and repairs can be made easily. Notwithstanding the loss sustained, and the handicap to development, the Alta will continue to operate.

During May the Tomboy shipped 45 cars of iron concentrate, and the Smuggler 68 cars of iron and flotation concentrates.

IDAHO

Gilmore.—The Pittsburg-Idaho Co. in Lemhi county has issued a brief report for 1917. Cash receipts from ore shipped totaled \$199,060. Operations cost \$247,208, making a loss of \$48,148. Dividends absorbed \$65,524, so the balance of \$182,409 from 1916 was reduced to \$68,738. Current assets amount to \$47,465, and liabilities \$91,187. Causes of the loss were delay in delivery in power machinery, water in the mine, and transportation difficulties. On May 1, 1918, the outlook is better, as the power-plant is working, sinking to 700 ft. is under way, and silver is \$1 per ounce.

Kellogg.—The Pine Creek branch, 9.3 miles long, of the O.-W. R. & N. Co. is to be completed at once. This will result in large ore shipments from the Constitution, Highland-Surprise, Douglas, and Nabob mines; but at least 12 mines will benefit therefrom.

On July 5 the Caledonia Mining Co. pays 3c. per share, equal to \$78,150.

Mullan.—A 150-ton plant is being erected by C. L. Hewitt at the Nine Mile mill to concentrate 60,000 tons of coarse tailing, 20 years old, from the Tamarack & Custer and Rex mines. The average content is 6% lead and 9% zinc. Jigs, tables, and flotation cells will be used.

Porthill.—The Idaho-Continental has accumulated 1400 tons of \$100 lead-silver concentrate in 50 days. This is to be hauled by truck 26 miles to Porthill for shipment to smelters.

Wallace.—Reports from Spokane state that shares in the Hypotheek M. & M. Co. jumped from 4 to 22 cents within two months, and the local Stock Exchange is making an investigation. An option had been given on 1,100,000 of the 2,000,000 shares to New York people, at 15c. a share. After this the price bounded up.

MICHIGAN

Houghton.—Calumet & Hecla reports as follows:

Mines	Copper in May, pounds	Five months, pounds
Ahmeeek	2,516,660	11,674,353
Allouez	715,427	3,353,637
Calumet & Hecla	6,008,589	31,105,504
Centennial	213,848	1,096,785
Isle Royale	1,395,242	5,861,931
La Salle	201,117	875,395
Oscoda	1,485,563	6,794,897
Superior	140,944	842,199
White Pine	267,342	1,166,940

MISSOURI

Joplin.—Production of the region last week amounted to 6555 tons of blende, 298 tons of calamine, and 1172 tons of lead. Prices averaged \$52, \$30, and \$87 per ton, respectively. Total value was \$452,254, making \$11,194,168 for 24 weeks. Missouri contributed \$98,572.

There is a shortage of underground men in the district, especially shovelers.

The 250-ton (per shift) mill of the Grayson M. & M. Co., 5 miles south-west, is nearly complete. H. H. Hughes is in charge.

Sarcosis.—The Flannery Zinc Co. is putting in a 75-hp. Diesel engine and duplex-plunger pump to drain its mine. This is a new arrangement for this field.

MONTANA

Giltedge.—A new cyanide mill has been completed and will be operated by E. B. Coolidge of Maiden and his Lewis-town associates. It is intended to first treat old tailing that assay \$1.90 gold per ton. Later it is hoped that much low-grade ore that is exposed can be worked at a profit.

The Mammoth mine and mill has been overhauled and will be operated this summer by N. J. Littlejohn of Lewis-town.

Grass Range.—The Ford Creek Oil Co.'s well is down 700 ft. Drilling is being continued. A small flow of gas has been encountered.

Lehigh.—No. 2 mine of the Cottonwood Coal Co. is now producing. This is a drift mine, consequently expenses are low. Lehigh is now producing 1000 tons of coal per day, mostly consumed by the Great Northern Railway.

Lewistown.—The Hanover plant of the Three Forks Portland Cement Co. is completed and has started to make cement. The rated output is about 25,000 bbl. per month. Gypsum wall-plaster is also made by the company.

The well of the Judith Oil Co., 12 miles east of Lewistown, is down 700 ft. A strong flow of water has interfered with progress, and the well may be abandoned.

Winifred.—Drilling has been started by the Kansas Montana Oil Co. with a standard rig a few miles north-east of town. The Home Oil Co. has also purchased a rig and expects to start drilling soon. The oil-sands lie 2000 ft. deep, and the structures have been reported on favorably by several prominent geologists.

NEVADA

Dayton.—The Como Consolidated Mining Co., which is operating 10 miles from here and 14 miles south-east of Virginia City, has made its first clean-up. From 1400 tons of ore in 20 days, gold worth \$5987 was sold and \$5000 is

absorbed in the cyanide plant. Future monthly yields are estimated at \$25,000, of which \$15,000 will be profit. The mine is opened to a depth of 360 ft. The mine is fully equipped, including electric power and 90-ton mill.

Tonopah.—Production of some of the local mines in May are as under:

Mine	Tons	Silver, oz.	Gold, oz.	Profit
Belmont	9,320	119,671	1,222	\$66,011
Tonopah	15,235	121,950	1,190	53,950
Jim Butler	2,160	41,552

Tybo.—The first 100-ton unit of the Louisiana Consolidated company's mill, 65 miles north-east of Tonopah, is working. Concentrate is said to assay 50% lead, 80 oz. silver, and \$20 gold per ton. Five tons of \$100 lead ore is also being mined daily.

OKLAHOMA

Douthat.—Twenty drills are busy south and east of this place, in an area hitherto disregarded.

Picher.—Oklahoma mines produced 5086 tons of blende and 947 tons of lead last week, valued at \$337,862.

SOUTH DAKOTA

Deadwood.—Work has been resumed at the Echo property in the Maitland district. A power-line has been extended to the mine and the shaft will be continued to a depth of 500 ft. Equipment includes a hoist and compressor.

The Cutting company has made arrangements to install a hoist and sink 500 ft. The gold-silver ore has been developed by tunnels. It is intended to sink and then drive laterals. The ground adjoins the Homestake on the west.

Lead.—The Bismarck mill at Flatiron has been placed in commission with a daily capacity of 40 to 50 tons. This will be increased to 100 tons as soon as the mine warrants it. The ore contains gold and silver, and is said to be of good milling grade. In addition, tungsten ore is found on the property.

Roubaux.—The Custer Peake Copper Co. will resume work. The shaft will be deepened to 500 ft. In addition, the company will purchase the Jungle mine adjoining, on which copper ore has been opened. The concentrator will be re-modeled.

Tinton.—After an idleness of nearly ten years work has been started at the Tinton company's property in the Nigger Hill district. Development shows a large deposit of low-grade tin. The property is equipped with a concentrator, which will be repaired. It is expected that the ore can be handled at a profit.

UTAH

Alta.—The Alta Tunnel & Transportation Co.'s tunnel is in 3408 ft., with 142 ft. to go to cut the Prince of Wales fissure. The face is 1140 ft. below the outcrop. Lead-silver seams are being cut by the tunnel at present.

Dugway.—About 30 miners are employed in this district at present. Several developments are said to have been good. Ore contains lead, copper, and silver.

Garfield.—Employees (500 of the 1600) at the A. S. & R. smelter here have decided to demand a flat raise of \$1 per day. Wages vary from \$3.15 to \$6.65 per 8-hr. day.

Park City.—On July 1 the Judge M. & S. Co. pays 12½¢ per share, equal to \$60,000. This makes \$120,000 for the current year and \$2,190,000 to date.

Tintic.—Chief Consolidated is to start diamond-drilling in the northern and eastern sections of its property. H. E. Horn is in charge of the new exploration work.

WASHINGTON

Leadpoint.—The Lead Trust mine near here has been acquired by a syndicate of Grant county men, who are to

spend \$40,000 in new machinery, including a mill. F. J. Barrett of Ephrata is largely interested, also J. C. Callahan, who may become superintendent.

Northport.—The Electric Point company has opened ore at a depth of 800 ft. Reserves are between 60,000 and 80,000 tons. A survey is to be made for construction of a railroad to connect the lower terminal of the aerial tram at Leadpoint with the Great Northern line at New Boundary. The distance is 10 miles, and the line may cost \$150,000.

At the annual meeting of the Northport Smelting & Refining Co., J. J. Day was re-elected president, E. Boyce, vice-president, and E. R. Day, secretary-treasurer. The Hercules and Tamarack & Custer companies of Idaho are the largest shareholders in the smelter.

CANADA

British Columbia

Hedley.—The Hedley Gold Mining Co. pays 15¢. per share on June 29.

Quesnel Forks.—The Ward-Hopp suit, which has been engaging the attention of the Legislature and the Courts of British Columbia for years and which is familiar to Canadian mining men, has assumed a new phase. In a recent judgment, the Court of Appeals of the Province found in favor of the plaintiffs—R. T. Ward and his associates—thus reversing the decision of Justice W. A. Macdonald, in the lower Court, whose verdict was that the placer-mining leases (the Bullion mines at Quesnel Forks) in dispute were properly the property of the defendant, John Hopp et al. It is expected that the case will be appealed by the latter, possibly going to the Supreme Court of Canada, and thence to the Privy Council of the Empire. The dispute is a long one, but includes such phases as concentration of work, lease rights, staking supposedly-abandoned ground, injunctions against working, re-staking, and forfeiture.

General interest in platinum has been aroused among local prospectors. The metal occurs associated with placer gold in this region. John Hobson, when operating the Bullion Hydraulic Gold Mining Co., recovered a small quantity each year. The discovery of its source is one of the matters which, it is believed, will be investigated by a party consisting of J. B. Tyrrell, Robert A. Bryce, and Gordon Taylor. Regarding platinum in the Cariboo it is interesting to quote William Fleet Robertson, Provincial Mineralogist, in his annual report for 1902, when he said: "I found that there were very small quantities of platinum in the Fraser River bars. I traced this up to Quesnel, where the Quesnel river enters the Fraser, above which point I could find but little in the Fraser river, as it chiefly seemed to be brought in by the Quesnel, which was traced up to Horsefly." He adds that he knows of no platinum occurring in place in Cariboo, but that British Columbia has platinum occurring with placer gold in Dease Lake, Cassiar, in considerable quantities and also in the Tulameen district, in which latter district it also has been found in place.

Mining men and the public generally in some sections of the British Columbian interior are agitating for some celebration of the 60th anniversary of the discovery of gold in the Cariboo district and the building of the famous Cariboo road. The movement started at Clinton, and is being met with favor, it being felt that something should be done to mark and commemorate an event of so much importance and interest as to merit a few pages in Canadian history, particularly in the mining development of Western Canada.

Trail.—The Consolidated M. & S. Co.'s reduction works here now employs 1100 men, who receive \$130,000 monthly. Ore smelted amounts to over 4400 tons per week.

Ontario

Cobalt.—During May the Nipissing extracted silver worth \$338,347 from 195 tons of high and 7306 tons of low-grade

ore. Including custom metal, there was shipped 538,231 oz. Development at No. 73 shaft was favorable, several new veins being found. They are not wide, but one is from 2 to 4 in., assaying between 2000 and 3000 oz. per ton. The Nipissing output for five months is \$400,000 ahead of the same period of 1917.

Fort Matachewan.—A complete report on this district has been prepared by A. G. Burrows of the Bureau of Mines. It is considered disappointing.

It is said that the Mining Corporation of Canada is negotiating for purchase of the Davidson mine. This company has secured an option on the water-power in the district, amounting to 2000 horse-power.

A diamond-drill is at work on the Colorado Ontario property (Otisse) in this district. Twenty men are employed at this mine.

There is promise of considerable activity here this season. Gold claims staked number close to one thousand, upon which certain work must be done. Confusion exists between some old and new holdings, due to conflicting staking. The Otisse and Davidson groups may be consolidated. Machinery is being hauled to the former.

Porcupine.—Hollinger Consolidated paid 1%, equal to \$246,000, on June 17. This is the first distribution for 15 months.

McIntyre-Porcupine produced gold worth \$430,000 during the first quarter of 1918. A dividend of 5%, equal to \$180,000, was paid on June 15.

KOREA

Seoul.—In Mosan district of northern Chosen a deposit of iron ore has been discovered, estimated to contain 200,000,000 tons. The Mitsubishi company controls most of it. Country is rough, and recent completion of a railway nearby will aid development.

Ulsan.—Recent returns from the Oriental Consolidated are as follows:

Month	Tons	Gold yield	Net profit
February	22,730	\$123,813	\$46,038
March	25,830	128,754	47,950
April	24,067	130,405
May	134,000

The Maibong tube-mill plant extracted 95.4% and the Taracol cyanide plant 87.3%.

MEXICO

Baja California

The well-known deposit of manganese on the coast of Lower California, near the town of Mulegé, opposite the port of Guaymas, have been turned over to Enrique Breceda under a so-called 'provisional permit,' being in effect an exclusive concession for a period of six months, counting from February 26 last. The details of the concession are published in the official organ of the Department of Mines, called the 'Boletín Minero,' Vol. 5, No. 2, recently issued. The concessionaire is required to produce not less than 200 tons monthly of manganese ore, and is obliged to pay a royalty of ₧3 per ton (metric) to the Government, plus 50 centavos per ton to cover the costs of official inspection. The mining rights relate only to the residual accumulations over the veins and to detrital deposits at lower levels, at places known as Point Concepción, Point Aguja, and Trinidad, all in the municipality of Mulegé. The total output under the concession is limited to 6000 metric tons.

Chihuahua

Ciudad Juarez.—A recent U. S. Consular Report states that there has lately been organized here a company under the name of Oficina General Ensayes to conduct an assay-office and chemical laboratory. Modern apparatus has been installed, the establishment being said to be the largest and best equipped in northern Chihuahua. The machinery was mostly purchased in the United States.

PERSONAL

Note: The Editor invites members of the profession to send particulars of their work and appointments. This information is interesting to our readers.

Albert Sauveur is in Paris.

W. F. Ferrier is at Ottawa.

Tyson S. Dines, of Denver, is here.

A. G. McGregor is at Jerome, Arizona.

James C. Ray is Captain in the 603rd Pioneer Regiment.

Robert H. Barrage is Lieutenant in the 27th Engineers.

Harold P. Taylor, of Douglas, Arizona, was here during the week.

Donald M. Liddell is Captain, with the Aircraft Board, New York.

G. L. Sheldon returns to Ely, Nevada, from Montana, early in July.

Kenzo Ikeda, with Fujita & Co., Osaka, is on his way back to Japan.

R. J. Glendinning, of Salt Lake City, was in San Francisco this week.

D. J. Argall has left Juneau temporarily and is now at La Jolla, California.

Simonds & Burns, mining engineers of New York, have dissolved partnership.

Scott Turner, Lieutenant in the Naval Reserve, is stationed at Cleveland, Ohio.

Charles W. Wright is Captain in charge for the American Red Cross in Sardinia, Italy.

R. S. Ammen, of the Cayuse Gulch mine, in Siskiyou county, is visiting San Francisco.

William J. Hayes is mining engineer to the Compañía Minera Choco-Pacífico, at Andagoya, in Colombia.

W. G. Miller, Provincial Geologist of Ontario, has gone to London to represent Canada on the Advisory Board of the Imperial Mineral Resources Bureau.

Melville F. Coolbaugh, professor of chemistry at the Colorado School of Mines, has gone to Washington, where he will serve as chemist for the Government.

Charles S. Vadner has gone from Reno, Nevada, to Tucson, Arizona, where he will be engaged in research work on manganese for the U. S. Bureau of Mines.

William Wraith, general manager for the International Smelting & Refining Co., returned to Salt Lake City on June 15 after an absence of several months in South America.

C. L. Berrien, assistant general superintendent of mines to the Anaconda Copper Mining Co., has received a commission as Major in the engineer department of the Army and expects to leave for France soon.

Roger Taylor has been appointed to the Ordnance Reserve Corps, and is therefore severing his connections with the engineering firm of Frederic Del' Hone & Co., of which he has been a member for 2½ years.

James Douglas died at New York on June 25, at the age of 81. Further reference to this deeply regrettable event will be made in due course.

Frederick B. Reece died of wounds received in action on April 20 in France, where he was serving in the Royal Flying Corps, although he first joined the Artillery in the early part of 1915, being promoted to Captain. He was a graduate of the University of California, although an Englishman by birth. The article on 'Oils Used in the Flotation Process,' appearing in our issue of May 1, 1915, was written by him in London just before he received his commission. He was a young engineer of high character and much promise, which he fulfilled by giving his life for his country at the front of battle.

THE METAL MARKET

METAL PRICES

San Francisco, June 25

Aluminum-dust, large and small lots, cents per lb.	65-70
Antimony (wholesale), cents per pound	15
Copper, electrolytic, cents per pound, in carload lots	23½
Copper, electrolytic, cents per pound, in small quantities	24½
Lead, pig, cents per pound	8.07½-0.07½
Platinum, Government price, per ounce	\$105
Quicksilver, per flask of 75 lb.	\$110
Spelter, cents per pound	9½
Zinc-dust, cents per pound	17½

Antimony, as discussed on June 24 before the U. S. Tariff Commission, will be found on page 899 of this issue.

ORE PRICES

June 25

Antimony, 45% metal, f.o.b. California, per unit	\$110
Chromite, 38 to 45% Chromium, per unit	\$1.25-\$1.50
Magnetite, crude, California, per ton (nominal price)	\$7.00-\$8.00
Manganese, domestic, 35 to 54%, f.o.b. South Chicago, per unit (Government price, effective May 29)	\$0.86-\$1.30
Manganese, domestic, 35 to 54%, f.o.b. South Chicago, per unit (Government price, effective May 29)	\$1.01-\$1.45
Import licenses for gypsum from overseas have also been revoked on and after June 11, except on sailing vessels or barges.	

Molybdenite, per lb., 90% MoS₃..... \$1.25
 Pyrite, per unit of sulphur, cents..... 28
 Tungsten, 60% WO₃, California, per unit..... \$24
 Imports of chrome are to be restricted, according to an order of the War Trade Board, dated June 13. To provide for current demand, pending development of domestic deposits, imports from Cuba, Guatemala, Newfoundland, and Brazil will be permitted, not exceeding 45,000 tons up to March 31, 1919; and from New Caledonia up to 10,000 tons prior to December 31, 1918. Shipments overland from Canada (or by lake), and Mexico, or as return cargo from Europe, will be allowed under certain conditions of loading. Licenses for import of chrome from overseas have been revoked as to shipments made after June 13, 1918.
 Import licenses for gypsum from overseas have also been revoked on and after June 11, except on sailing vessels or barges.

EASTERN METAL MARKET

(By wire from New York)

June 25.—Copper is unchanged. Lead is quiet, though firm. Spelter is strong and higher.

SILVER

Below are given official (not Government) quotations, in cents per ounce of silver, 999 fine. In order to make prompt settlements with smelters and brokers, producers allow a discount from the Government price of \$1, hence the lower price. The Government has not fixed the general market price at \$1, but will pay this price (as from April 23, 1918) for all silver purchased by it. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the current rate of exchange.

On September 21, 1917, the Government fixed copper prices at 23.50c. per lb. for large lots and 24.67½c. for small lots, effective until June 1, 1918. On this date the prices were re-fixed until August 15, 1918. Quotations in cents per pound are as under:

A probable early revision of copper prices is announced from the East. Import licenses for copper ore from overseas, save from Cuba, have been revoked by the War Trade Board, except for shipments made prior to June 10. The reason for this is to bring about the import of matte instead of the bulkier crude ore.

LEAD

Lead is quoted in cents per pound, New York delivery. Government metal receives 7c. per lb. until August 6.

ZINC

Zinc is quoted as spelter, standard Western brands, New York delivery, in cents per pound. On May 25, 1918, the Government fixed prices until September for grade A spelter at 12c. per lb. for itself and the open market. Lower grades can make their own prices as usual. Sheet-zinc is fixed at 15c., and plate at 14c. per pound.

Zinc ore was \$2.50 per ton stronger at Joplin, Missouri, last week. Average sales were \$32 per ton, but the range was from \$40 to \$55.

C. E. Sieenthal, of the U. S. Geological Survey, suggests suspending production of prime Western spelter until the surplus is exhausted.

With reference to the Canadian zinc bounty, this applies only up to 8c. per lb., that is, if a 2c. bounty sends the price received above that amount, it is reduced or entirely eliminated. The object is to ensure as far as possible a price of 8c. per pound.

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, according to quantity. The Government is taking 40% of the United States quicksilver output, paying therefor \$105 per flask. Outside of this business the competitive market can make any price as usual. Prices, in dollars per flask of 75 pounds:

ORES

Antimony: There have been no developments.

Manganese Alloys: Ferro-manganese is quiet, most consumers being well covered by recent large purchases. Domestic alloy is held at \$250, delivered, for 70% material plus \$4 per unit above this standard. Spiegel-eisen is quiet and unchanged at \$75 furnace for 10% alloy, plus \$3.50 per unit above this standard.

Molybdenum: The market is unchanged. Inquiry, outside of some for export, is light.

Tungsten: Quotations are nominally unchanged. Demand is small, consumers being well covered, apparently.

The Cassel Cyanide Co. of Glasgow paid an interim dividend of 1s. (24 cents) on June 1. On the 705,000 shares issued this amounts to \$169,200. Distributions have been made since 1891.

Eastern Metal Market

New York, June 19.

None of the markets is characterized by special activity so far as the volume of sales is concerned, but all except tin and copper are strong and higher.

Conditions on the surface appear unchanged in copper, but dissatisfaction prevails as to prices and costs.

Tin continues to ease slightly and sales have been in small volume.

Lead is scarce but has advanced decidedly.

Zinc is strong and higher on restricted offerings.

Antimony has advanced, and is in fair demand.

The steel-price schedule for the period commencing July 1 will be discussed at Washington June 21 between the War Industries Board and the iron and steel manufacturers' committee. A preliminary meeting of the latter is being held today in New York. Costs in the next quarter will be higher, the freight advances adding \$1 to \$1.50 to the cost of pig-iron, says 'The Iron Age.' The coming price-conference is plainly dwarfed by the changes involved in the new Government control of iron and steel distribution, which will probably be more radical than the trade was willing to believe. Cabled orders from American headquarters in France in the past week call for a staggering amount of steel, including hundreds of locomotives and many thousands of cars. The Railroad Administration is also planning to buy 400 more locomotives and to increase by 40% the order for 100,000 freight cars already placed.

COPPER

The question of an upward revision in the copper price of 23.50c. continues to be an absorbing topic and it is evident that producers are by no means satisfied with the present status. A meeting of the leading producers was held in New York yesterday, but the object has not been given out. What is regarded as a significant fact is that as yet the President has not officially announced the re-establishment of the present price as effective from June 1 to August 15, although the War Industries Board has so recommended. An argument now being used is that the freight advance is to cause an increase in costs of at least 1c. per lb. Many believe a readjustment is yet possible, either by August 15 or before. The demand is strong and consumption is on a large scale. Refinery output in May was larger than that in April and the monthly average is now said to be about equal to that of 1917. It is asserted, but not confirmed, that not less than 90% of the present output is being absorbed by the United States and its Allies. Imports of copper have been 91,000 tons to May 1 this year, as contrasted with 85,000 tons to May 1, 1917.

TIN

The tin market continues to ease, so far as may be judged from its extreme dullness and inactivity. There has been very little doing the past week. A fair inquiry for off-grades has been evident, and some business in this description has been done, in fact, more of such tin could have been sold had it been offered. Only light sales have been made in future shipments from the Far East. These sales were for July and August shipment, with some for September, all at about 80 to 81c. per lb., as compared with 82c. a week ago. Arrivals at Atlantic ports, up to June 14 inclusive, have been 465 tons, while those at Pacific ports to June 15 inclusive, have been about 2490 tons, as reported by the New York Metal Exchange. So much more tin is coming direct via Pacific ports that arrivals there are more important than formerly, and are being prominently and daily reported. It

is estimated that about 5000 tons is afloat from Eastern ports. The London market has not changed since last week, spot Straits having been quoted yesterday at £329 per ton.

LEAD

The market for lead continues strong, but was made decidedly stronger on Monday by the advance of the American Smelting & Refining Co. in its quotation from 7.25c., New York, to 7.82½c. This represents an increase of \$11.50 per ton, or 57½ points, and is quite unusual. It was the cause of considerable surprise. The market is therefore quotable at 7.75c., St. Louis, or 7.82½c., New York, but is more or less nominal, the metal being rather scarce. The same feature that has been prominent in this market for some weeks continues, namely, restricted supplies for prompt June and July shipment. Buyers have been desirous of obtaining as much lead as possible before the advance in freight rates becomes effective, and this has been one strong factor in the advancing market. Imports of lead in April were 6720 gross tons, making the total, for the first four months of this year, 32,315 tons, against 16,147 tons for the same four months of 1917. Exports were 6925 tons, as against 8669 tons in April 1917.

ZINC

Many believe that the zinc industry has passed through its period of illness, that it is now convalescing, and that it has nearly, or soon will attain robust health again. It is certain that it is becoming stronger daily. Yesterday as high as 7.75 to 7.87½c. was bid for prime Western for early delivery, and 7.87½c. was offered for July shipment. Few dealers are quoting less than 7.75c., St. Louis, or 8c., New York, for early delivery; and this may be regarded as the market. For third quarter 8c. is quoted, St. Louis, or 8.25c., New York. Sales have been made of one or two small lots at 7.75c., St. Louis, for June and early July shipment, but, for the most part, offerings are meagre for any position. Some predict that prime Western will soon sell at 8c., St. Louis, or 8.25c., New York. The entire situation is decidedly strong and eminently satisfactory. The feature of news of the week has been the suggestion from C. E. Sieben-thal of the U. S. Geological Survey, that certain Western producers shut-down for two or three months, allow their men to assist Western farmers in the harvesting of crops, and thus cut down the production of grades C and D zinc. In this way it is believed that the market price of these might then more nearly approach a relative parity with that of grade A. The proposition, while surprising and unusual, is not regarded seriously, nor is it likely to be acted upon. Exports this year have been much less than those in 1917. To May 1, 1918, the total has been 33,158 gross tons, against 71,244 tons to May 1, 1917.

ANTIMONY

The market is stronger at 13.25c., New York, duty paid, for Chinese and Japanese grades, for prompt and early delivery. This is due to the recent fairly large sales and to the greater interest on the part of consumers who desire to purchase before the freight rates advance the price.

ALUMINUM

For No. 1 virgin metal, 98 to 99% pure, the Government maximum price is 33c. per lb. for 50-ton lots, 33.10c. per lb. for 15 to 50 tons, and 33.20c. per lb. for 1 to 15 tons. The same prices rule for scrap aluminum.

Production of ferro-manganese in the United States in May, by blast and electric furnaces, was 35,790 tons, a record. The spiegelisen output was 17,844 tons.

Book Reviews

Chemical Analysis of Iron. By A. A. Blair. 8th edition. Pp. 318, ill., index. J. B. Lippincott Co., Philadelphia, 1918. For sale by 'Mining and Scientific Press.' Price, \$4.

Since 1912, when the last edition appeared, there have been many improvements in the analysis of iron ore, limestone, coal, coke, clay, sand, iron, steel, and alloy metals. Since 1914, steel and alloy metals have become highly important, and a handbook containing up-to-date methods of analysis is welcome. In the handling of 60,000,000 tons of iron ore, manufacture of 35,000,000 tons of steel, and hundreds of thousand tons of alloy steels in a year in this country, it might be said that the whole business is based on careful analyses, which must be performed rapidly. The first 54 pages of the new book describes the apparatus and reagents used in determinations; the remainder is devoted to methods of analysis. Rapid methods are given in many cases, including the important elements sulphur, silicon, phosphorus, and manganese. The determination of carbon in iron and steel occupies 45 pages, including description of various apparatus needed. For those interested in the rarer minerals, the analysis of tungsten, vanadium, molybdenum, and chromium in steel is of value, also ferro-tungsten, ferro-molybdenum, ferro-vanadium, ferro-chrome, ferro-silicon, and ferro-manganese. Iron-ore analysis receives 43 pages, and is fully discussed; while fuel and fluxes in blast-furnace reduction are given due attention. A feature of the analytical work is a good sketch of nearly all apparatus used, a great aid in following each method. Generally, we consider this work timely and valuable.

Northwest Mines Handbook. Edited by Sidney Norman. Pp. 318, illustrated. Sidney Norman, Spokane, Washington, 1918. For sale by 'Mining and Scientific Press.' Price, \$5.

The North-west, locally termed 'The Inland Empire,' contains a large number of important mines, mostly base-metal producers. The work before us is a reference of this region. Alphabetically arranged is given the capital, officials, property, development, and other details of 750 companies in Idaho, 300 in British Columbia, 300 in Washington, 130 in Montana, and 130 in Oregon, or a total of 1610. Preliminary to each State are statistics of its production and a brief chapter on its geology, the latter by some engineer of repute. In describing mines and company operations, commencement of each department is shown by bold-face type, but there is no paragraphing. For instance, the Bunker Hill & Sullivan occupies 2½ pages, but is one long paragraph. However, the matter is clear enough. Where possible, data are included up to April 1918. In Washington, the Stevens County copper and magnesite deposits, now attracting much attention, are described; also the Electric Point lead area. Only those properties in Montana in which Spokane people are interested are included, thus the big mines are not available. As a mining State, Oregon is frequently overlooked, so it is good to see its mines listed herein. In the description of the magnesite deposits of Washington, it is prophesied that as it costs \$12.50 and under per ton to quarry and produce calcined ore in the northern State, and \$18 to \$25 in California, at a market-price of \$20 per ton, California will probably be eliminated from the market. Two pages descriptive of Spokane, the centre of mining in the North-West, complete a handy compilation.

Safeguard the Gateways of Alaska: Her Waterways. By E. L. Jones. Special publication No. 50 of the U. S. Coast and Geodetic Survey, Washington, 1918.

This is a useful and well-illustrated publication.

Mining Decisions

Coal Land Entry—Single-Entry Limitation

Under Revised Statutes Section 2350 which authorizes but one coal entry by the same person, association or corporation, a corporation which received the benefit of an entry made by an individual, cannot make another entry, either itself or through an agent, even though both entries combined do not exceed the maximum area allowed by statute.

Union Coal and Coke Co. v. United States (Colorado), 247 Federal, 106.

Oil and Gas Lease—Forfeiture Clauses

An oil and gas lease containing a stipulation on the part of the lessee to commence operation on the premises within a year from a certain date or pay for delay, conferred on the lessee an option to drill or pay, and a failure to do either rendered the same forfeitable at the choice of the lessor. Where such a lease contains a clause reserving to the lessee the right at any time to remove all his property and re-convey the premises, and thereby render such lease null and void, it was held that a corresponding right existed in the lessor before development to compel a surrender.

Melton v. Cherokee Oil & Gas Co. (Oklahoma), 170 Pacific, 691. February 12, 1918.

Mining Corporation—Dissolution—Sale of Assets

When a majority of the stockholders of a mining corporation whose charter had expired, authorized a sale of all its properties to a new corporation, having the same directors, for a stock consideration, and minority stockholders objected to the sale as being for an inadequate price and not for cash, a showing that the properties had first been fairly and openly offered for sale at public auction to the highest cash bidder and that no bids were received, is enough to justify the action of the majority stockholders. They as well as the minority are entitled to protection.

Geddes v. Anaconda Copper Mining Co. (Montana), 245 Federal, 225.

Oil Lease—Separated Tracts—Failure to Drill on One

Two widely separated tracts of land were included under one oil lease which requires the lessee to drill within two years three wells "on the above described lands." The lessee drilled all the wells on one tract and did nothing with the other for more than ten years. Held, on suit to cancel the lease, brought by a subsequent owner of the second tract for failure of the lessee to drill wells thereon, that the Court's decree on the above state of facts should require the lessees to drill on said land within a reasonable time to be fixed by the Court, with a penalty of forfeiture if such work be not done within the decreed time.

Alford v. Dennis (Kansas), 170 Pacific, 1005.

Oil Placers—Exceptions from Withdrawal Order

Where contiguous oil-placer claims, not exceeding five in number, had been located by an association of eight persons, prior to the executive withdrawal of 1909, and development work had been prosecuted on one claim diligently and over \$20,000 expended in preparations for drilling on the other claims, and the drilling in progress on one claim, as demonstrated by the subsequent discovery and extraction of oil, tended to develop the remaining claims, valid rights were vested in the locators that were not affected by the withdrawal order and were confirmed by the provisions of the Pickett Act, enacted by Congress June 25, 1910. Order of the trial court appointing a receiver reversed.

Consolidated Mutual Oil Co. v. United States (California), 245 Federal 521.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

MAGNETIC BRAKES

The principle of the type of magnet which has been so successfully incorporated in the design of magnetic controllers by the Westinghouse Electric & Mfg Co., of East Pittsburgh, Pennsylvania, has been employed by that company in a new design of magnetic brakes developed for use with mill, crane, and hoist-motors. The use of a clapper-type magnet eliminates all moving parts within the coil and the consequent wear, sticking, or damage to insulation.

means for making adjustment for shoe-wear are provided. In case adjustments for shoe-wear should be neglected a safety feature has been introduced so that the brake does not fail to hold the load, but the magnet will not release the grip on the brake-wheel. This insures proper brake operation and the elimination of accidents due to the slippage of the brake-wheel. The simplicity and accessibility of the few parts of these brakes are shown in the accompanying illustrations. An interesting description, interspersed with many engravings, is given in the manufacturer's

BRAKES AND BRAKE-WHEEL

MAGNETIC BRAKE APPLIED TO WINCH

The modified and improved 'type A' alternating-current brake with which the trade is already familiar and the new 'type B' direct-current brake are similar in operation and have common parts throughout except for the armature-lever and magnet. These brakes are characterized by the quickness of their operation. They respond almost instantly, releasing when the power is applied and setting when the power is cut off. This is due to the design of the operating magnet, which gives a high initial pull and a small distance of travel (1 to 1 in.). Their operation is similar. When voltage is impressed on the motor the magnet is energized and the magnet-armature level overcomes the pressure of the compression springs through a toggle and releases the brake-shoe grip upon the brake-wheel. While the magnet remains energized the brake-wheel is allowed to rotate freely. As soon as the current is shut off from the motor the brake-magnet releases and the compression springs force the shoes against the brake-wheel, bringing the motor quickly and smoothly to rest without shock or jar. The compression exerted by the springs can be adjusted easily so that any holding or retarding torque up to the full capacity of the brake can be obtained for equal-braking effort for both directions of rotation. Simple

turer's leaflets 1750 and 1751 on the types A and B brakes, respectively.

The Ingersoll-Rand Co., 11 Broadway, New York, has recently issued the following new literature: Form 4039, 8-page bulletin on Leyner shank and bit punch for punching out holes in bits and shanks of hollow drill steel; form 901, 4-page flyer showing the complete line of 'Little David' pneumatic tools, with tables of sizes and capacities given and also illustrations showing all the tools and their applications; form 9028, 18-page catalog illustrating and describing equipment for sugar factory and refinery service, together with a separate Spanish edition available for those who desire it; form 9010, 4-page catalog on the 'Sergeant' ticket-cancelling box; form 901-1, a single-page flyer on the 'Little David' caulking machine; form 888, a 4-page flyer on the 'Little David' evaporator tube-cleaning and other labor-saving pneumatic tools; form 876, a single-page flyer on the Ingersoll-Rand barometric condensing plants; form 883 A, a single-page flyer on class 'FP' steam engines, horizontal centre-crank type with piston valves; and form 3015-1, 4-page bulletin on 'ER-1' portable mine car air-compressors.

COMMERCIAL PARAGRAPHS

The Emerald Coal & Coke Co., Pittsburgh, Pennsylvania, has increased its capital from \$2,500,000 to \$3,000,000 for expansion.

The Atlas Crucible Steel Co., Marine Bank Bdg., Buffalo, New York, has increased its capital from \$1,500,000 to \$3,000,000 for purposes of expansion.

The United Zinc Smelting Corporation, 99 John street, New York, operating at Moundsville, West Virginia, is drawing plans for the installation of a new furnace at its works.

The Mexican Mines Exploration Co., New York City, a Delaware corporation, has filed notice of increase in its capital stock from \$200,000 to \$500,000 to admit of proposed expansions.

The Maas & Waldstein Co., avenue R, Newark, New Jersey, will build a new nitrating plant at its chemical works. The structure will be two-story, about 56 by 126 ft., and is estimated to cost \$30,000.

The Southern Manganese Mining Corporation, Birmingham, Alabama, has been organized to operate manganese properties in this district. Theodore Swann is president, and R. L. Ingalls, vice-president.

The Sutton Chemical Co., Sutton, West Virginia, is planning to construct a new chemical works on the Elk river to cost about \$300,000. The plant will be used for the production of chemicals for the Government.

The War Department, Washington, D. C., has taken over the plant of the Charleston Alloy Steel Co., Belle, West Virginia, for a consideration of about \$500,000, and proposes to re-build the works for the manufacture of chemicals for explosives.

The Alabama Co., 808 Union Trust Bdg., Baltimore, Maryland, Edward N. Rich, president, has acquired iron ore property at Gadsden, Alabama, and plans to undertake extensive development work. It is proposed to operate the mines with a monthly output of from 12,000 to 15,000 tons.

About 100 acres of coal lands will be developed by the Dean Branch Coal Co., Bell Jellico, Kentucky, recently incorporated with a capital of \$25,000. The company proposes to install a plant to provide a daily capacity of about 200 tons. W. B. Johnston is president, and A. W. Babbage, vice-president.

Lewis F. Shoemaker & Co., Pottstown, Pennsylvania, is considering extensions at its structural steel works to double the present capacity. The plant is devoting considerable of its output to the production of material for steel vessels for the Government shipyards, under the jurisdiction of the Emergency Fleet Corporation.

The Standard Spar Mining Co. of America, at Marion, Kentucky, recently incorporated with a capital of \$500,000, is planning for the development of fluorspar properties consisting of about 100 acres. It is proposed to install an initial plant to provide for mining 100 tons daily. The plant will cost about \$20,000. J. L. Oxley and Frank G. Fox are interested in the company.

The Aluminum Castings Co., Cleveland, Ohio, is having plans prepared for a new plant to be erected on Harvard avenue, near Thirty-second street, to cost about \$400,000. The works will comprise a one and two-story structure, 100 by 200 ft., to form a foundry, pattern-shop, and other departments. A power-plant will also be erected. E. L. Allens is president and general manager.

The Bull Creek Coal Co., Prestonburg, Kentucky, recently organized, is planning to install a complete coal-mining plant for the exploitation of about 500 acres of coal proper-

ties. It is proposed to reach an output of approximately 500 tons daily. The plant is to include mining equipment, boilers, engines, pumping machinery, and electrical power equipment. E. A. Layne is treasurer.

A new plant for the manufacture of marine boilers for Government vessels, to cost about \$2,500,000, will be erected by the Newport News Shipbuilding & Dry Dock Co., Newport News, Virginia, on a site selected on the James river. The plant will consist of machine shop, foundry, boiler works, riveting plant, and other structures, including an electric power-plant for operation. The new works is expected to give employment to about 2000 men.

Electrical machinery, signal devices, and other equipment, to cost about \$32,000,000 will be purchased by the Interborough Rapid Transit Co., 165 Broadway, New York. The company has been granted permission by the Public Service Commission to issue bonds for \$37,700,000 for extensions and betterments, including transmission system, \$2,301,000; distributing system, \$5,585,000; electric sub-station equipment, \$3,870,000; new passenger cars, \$7,581,000; electrical equipment for cars, \$3,388,000; tunnels, \$1,312,000; interlocking signals and other signal equipment, \$3,371,000.

Two large ammunition plants for Government work are now in course of construction in New Jersey, at Morgan Station, near Perth Amboy, and near Mays Landing, respectively. The first is being erected by the T. A. Gillespie Loading Co., and consists of a site of over 2000 acres, the bulk of which will be used for the works. Construction at this plant has reached a point where a few of the units are ready for operation, and a number of new units are being built. When under full operation, the works will give employment to about 5000 hands. The other plant, near Mays Landing, is being erected by the Bethlehem Loading Co., Bethlehem, Pennsylvania, a subsidiary of the Bethlehem Steel Co. At this point work has been started on twelve units to form the main ammunition works. An electric power-plant will be constructed on a pile foundation for operating the works. The company also has arranged for a housing development, naming the village Belcoville.

Walter A. Zelnicker Supply Co., of St. Louis, has issued bulletin No. 237, listing a considerable amount of relaying rails ready for immediate delivery. The weights range from 100-lb. to 12-lb. rails. The firm also quotes crossings, frogs, switches, and other railway supplies, angle bars, girders, and a large assortment of second-hand quarry machinery. The list includes locomotives, large and small, electric locomotives, standard and narrow-gauge cars, gondolas, street cars, steam-shovels, both the railroad and traction type, and an unusually large assortment of air-compressors.

The American Smelting & Refining Co. is arranging for immediate erection of an addition to its works at Perth Amboy, New Jersey, to cost about \$10,000. The company is operating the plant at capacity. Particular attention has recently been given to employees' welfare, and the construction of a large club-house for workers at the plant, to cost about \$75,000, is under way.

The Blaw-Knox Co. announces its removal, on June 1, from the Rialto Bdg. to its new office and warehouse, 528-530 Second street, San Francisco. A quantity of steel forms for concrete construction, Blaw-Ransome concrete mixers, and Blaw clamshell buckets are carried in stock for immediate delivery.

Chas. Butters & Co., Ltd., 6400 Chabot Road, Oakland, California, will issue immediately a special catalogue describing the Jones-Belmont flotation machines. This apparatus affords high efficiency, and the catalogue will be of great interest to those who are interested in concentration of ores.
